AN INVESTIGATION OF THE PENETRATION OF PRESSURE
BELOW THE SURFACE OF A COMPRESSIBLE FLUID

[Following is the translation of an article by A. G. Bagdoyev entitled "Issledovaniya Zadachi O Pronikanii Davleniya V Glub' Szhimaemy Zhidkosti" (English version above) in Vestnik Moskovskogo Universiteta (Herald of Moscow University) Mathematics, Mechanics, Astronomy, Physics, and Chemistry Series, No 3, Moscow, 1957, pages 23-29]
Assume that pressure is exerted at a certain point 0 on the free surface of a compressible fluid. This is then propagated along this surface in the form of a shock wave (Fig. 1). We will assume that \( R(t) \) describes the propagation of the wave front and the distribution of pressure on the surface and is a known but arbitrary function of time. The pressure distribution in the depths of the fluid is then found with the aid of a quadrature /1/.

![Fig. 1](image)

1. Pressure distribution along a head wave.

In cases where the velocity of the front is greater than the velocity of sound in the fluid, the disturbed region will be bounded by the characteristic arc (the
head wave) AB and a circle of radius at (Fig. 1). Let us select an axis Or in the plane of the free surface and an axis Oz perpendicular to Or.

In the region ACB the pressure distribution takes the form:

\[ p(r_0, z, t) = \frac{1}{\pi} \int_0^{r_0^*} \int_0^{2\pi} \frac{(r, \varphi')}{r^2 + r_0^2 - 2r_0 r_0 \cos \varphi'} r' dr' d\varphi' + \frac{1}{\pi a} \int_0^{r_0^*} \int_0^{2\pi} \frac{\partial P_1(r, \varphi')}{\partial t} r' dr' d\varphi' + \]

\[ + \left[ \frac{1}{\pi a} \int_0^{2\pi} p_1(r_0^*, \varphi) \frac{dr_0^*}{dt} d\varphi + \frac{1}{\pi a} \int_0^{2\pi} p_1(r_0^*, \varphi) \frac{dr_0^*}{dt} d\varphi \right] \frac{d\varphi}{dz} \cdot (1,1) \]

where \( r_1^*, r_2^* \) are the roots of the equation

\[ r_{1,2}^* = R \left( t - \frac{\sqrt{r_1^* + r_2^* - 2r_0^* \cos \psi_1 + z^2}}{a} \right) \]

\[ t'_* = f(r_1^*); \quad t'_* = f(r_2^*) \]

\( f(r) \) is the inverse function of \( R(t) \), \( \psi_1 \) is the value of \( \psi \) for which \( r_1^*(\psi_1) = r_2^*(\psi_1) = j_0^* \). Then \( \psi_1 \) and \( j_0^* \) are found from the equations

\[ r_0^* = R \left( t - \frac{\sqrt{r_0^* + r_0^* - 2r_0 r_0 \cos \psi_1 + z^2}}{a} \right) \]

\[ 1 + \frac{1}{a} R' \left( t - \frac{\sqrt{r_0^* + r_0^* - 2r_0 r_0 \cos \psi_1 + z^2}}{a} \right) r_0^* - r_0 \cos \psi_1 = 0. \]  

(1,3)

The head wave may be expressed parametrically as the envelope of the elementary disturbances arising at a
point on the free surface at the instant of time $t'$ at which the wave front reaches it.

$$[r_0 - R(t')]^2 + z^2 = a^2 (t - t')^2,$$

$$R'(t')[R(t') - r_0] = a^2 (t' - t).$$  \hspace{1cm} (1.4)

The Eqs. (1.3) and (1.4) constitute a system of equations for the determination of $r_0^*$, $\Psi_1$, $t'$ and $z$ as functions of $r_0$ and $t$. It is obvious that in this case it is possible to set $\Psi_1 = 0$ and

$$t' = t - \frac{\sqrt{r_0^2 + r_0^2 + 2r_0^2r_0 + z^2}}{a}.$$

Then the Eqs. (1.4) will follow from (1.3) and for the determination of $r_0^*$, and $z$ there will remain the two Eqs. (1.3). Thus we have ascertained that $\Psi_1 = 0$ on AB. Substituting $\Psi_1 = 0$ in Eqs. (1.3) we obtain equations for $r_0^*$ and the equation of the line AB. Let us denote $\overline{r}_0^*$ on the head wave as $\overline{r}_0^*$. It is clear that this quantity may be found from the equations

$$\overline{r}_0^* = R \left[ \frac{t - \sqrt{(\overline{r}_0^* - r_0)^2 + z^2}}{a} \right],$$

$$1 + \frac{1}{a} R' \left[ \frac{t - \sqrt{(\overline{r}_0^* - r_0)^2 + z^2}}{a} \right] \frac{\overline{r}_0^* - r_0}{\sqrt{(\overline{r}_0^* - r_0)^2 + z^2}} = 0,$$  \hspace{1cm} (1.5)

which serve at the same time for the determination of the equation for AB: $z = z(r_0^*, t)$. In particular, if $R' = \text{const} = V_0$, then

$$\overline{r}_0^* = \frac{r_0 - \frac{a t}{M}}{1 - \frac{1}{M^2}}.$$
where \( R = \frac{V_0}{a} \). After substituting this value of \( \frac{V_0}{a} \) in the first of Eqs. (1.5), we get the equation of the head wave front:

\[
z = \frac{V_0 t - r_0}{\sqrt{M^2 - 1}}.
\]

Let us now find from Eq. (1.2) an expression for \( \frac{dr_*}{dt} \), which appears under the integral sign in Formula (1.1):

\[
\frac{dr_{1,2}^*}{dt} = \frac{R'}{1 + \frac{1}{a} R'} \left( t - \frac{r_{1,2}^* + r_0^* - 2r_0r_{1,2}^* \cos \psi + z^2}{a} \right) \frac{r_{1,2}^* - r_0 \cos \phi}{\sqrt{r_{1,2}^* + r_0^* - 2r_0r_{1,2}^* \cos \psi + z^2}}.
\] (1.6)

From Eqs. (1.6) and (1.3) it is clear that at the upper limit (\( \Psi = \Psi_1 \)) \( \frac{dr_*}{dt} \) becomes infinite.

All the integrals in (1.1), with the exception of the last two, vanish on the head wave AB. In the two exceptions the interval of the integration degenerates to a point while the integrand goes to infinity. From this it follows from among other things that in the case where the boundary condition is given in the form:

\[
p_1(r, t) = p_A(R)f_1(r/R),
\]

where \( R(t) \) is the radius of the front at the time \( t \), then the following equations will hold:

\[
p_1(r^*_1, t) = p_A(r^*_1),
p_1(r^*_2, t) = p_A(r^*_2).
\]
that is, the pressure distribution \( p(r_0, z, t) \) along the head wave AB does not depend upon the pressure distribution behind the front \( f_1(r/R) \).

![Diagram](image)

**Fig. 2**

To determine the pressure distribution over the head wave, in the general case, we must find the limit approached by the last two integrals in Formula (1.1) as we move to AB. We note that the entire continuous part of the integrand may be taken from under the integral sign after setting

\[
\phi = 0, \quad r_1^s = r_2^s = r_0^s; \quad t_1^s = t_2^s = t_0^s.
\]

in it. Thus the problem ultimately becomes one of finding the limit of the expression:

\[
\frac{1}{\pi a} \frac{p_1(r_0^s, t_0^s)}{z^2 + (r_0^s - r_0^s)^2} 2r_0 \int_0^{\phi_1} d\phi \int_0^{\phi} \left( r_2^s - r_1^s \right) d\phi.
\]  

(1.7)
where \( \overline{r}_0^* \) and \( z = z (r_0, t) \) are determined by Eqs. (1.5).

It is clear from (1.6) and (1.3) that only the function \( R(t') \) itself and its first derivative \( R'(t') \) enter into the integral in Formula (1.7). Aside from this, the values of the arguments of the functions \( R \) and \( R' \) in (1.7) approach \( \overline{t}_* \) as \( \psi_1 \rightarrow 0 \), that is, for every \( r_0, z \) and \( t \) belonging to \( AB \).

Let us consider the graph of \( R(t') \) (Fig. 2). From Eq. (1.5) we find \( \overline{r}_0^* \) and \( \overline{t}_* \), for fixed values of \( r_0, z \), and \( t \) on \( AB \).

In the neighborhood of \( r = \overline{r}_0^* \) and \( t' = \overline{t}_* \) we substitute the equation of the tangent at the point \( M \) for the curve \( r = R(t') \). This equation takes the form:

\[
 r - \overline{r}_0^* = R'(\overline{t}_*)(t' - \overline{t}_*)
\]

The equation for the determination of \( r_1,2^* \) now takes the form:

\[
 r_1,2^* - \overline{r}_0^* = R'(\overline{t}_*)(t - \frac{\sqrt{r_{1,2}^* - \overline{r}_0^* - 2r_{1,2}^* \cos \psi + z^*}}{a} - \overline{t}_*)
\]

We obtain an expression for \( r_1,2^* \) by solving this equation:

\[
 r_1,2^* = \frac{M^2 r_0 \cos \psi - \overline{r}_1 \pm \sqrt{(M^2 r_0 \cos \psi - \overline{r}_1)^2 - (M^2 (r_1^2 + z^2) - \overline{r}_1)(M^2 - 1)}}{M^2 - 1}, \quad (1.8)
\]

where

\[
 M = \frac{R'(\overline{t}_*)}{a}, \quad \overline{r}_1 = r_0^* + R'(\overline{t}_*)(t - \overline{t}_*).\]
We have the following expression for $\Psi_1$:

$$\Psi_1 = \arccos \sqrt{\frac{r_1 + \sqrt{(M^2 - 1)[M^2(r_0^2 + z^2) - r_1^2]}}{M^2 r_0}}.$$ 

When differentiating (1.8) over time it is necessary to take into account the dependence of $g_\pi$ on $t$. In performing this differentiation it is not difficult to see that the integrand will consist of some continuous function, which we will discard, plus a fraction. The numerator of this fraction is also a continuous function, but the denominator is a radical which also enters into Eq. (1.6), and which vanishes when $\Psi = \Psi_1$. As has been previously noted, the continuous part of the integrand may be taken from under the integral sign on setting $\Psi = 0$ in it. Thus the entire matter reduces to the calculation of the integral:

$$\int_0^\Psi \frac{d\Psi}{\sqrt{(M^2 r_0 \cos \Psi - r_1)^2 - [M^2(r_0^2 + z^2) - r_1^2](M^2 - 1)}}.$$ 

Substituting in the last integral $\cos \Psi' \approx 1 - \Psi'^2/2$, as is possible because of the smallness of $\Psi'$, and calculating the resulting tabular integral, we finally have along $AB$:

$$p(r_0, z, t) = \frac{p_1(r_0^2, t_e) \sqrt{M^2 r_0 - r_1} \left[ \frac{d\tilde{r}_1}{dt} - \frac{M \frac{dM}{dt}(r_1 - r_0)}{M^2 - 1} \right]}{a \sqrt{r_0 M^2}}.$$ 

(1.9)

where

$$M = \frac{R'(\tilde{t}_e)}{a}; \quad \tilde{r}_1 = \tilde{r}_0^2 + R'(\tilde{t}_e)(t - \tilde{t}_e).$$
and the pressure distribution along the head wave is given in terms of the elementary functions.

On the free surface $z = 0$, $\frac{x}{r_0} = R(t)$, and $p(r_0, z, t) = p_1(R, t)$. If $p_1 = \text{const}$ and $R'(t) = \text{const} = V_0$, we have for the pressure distribution along $AB$:

$$p(r_0, z, t) = p_1 \sqrt{\frac{M^2 r_0 - V_0 t}{r_0 (M^2 - 1)}}.$$  \hspace{1cm} (1.10)

The expression (1.10) was derived by A. Ya. Sagomonyan by the method of characteristics.

2. An Investigation of the Solution in a Half Space

It is interesting to investigate various particular cases of the definition of the law giving the pressure distribution on the surface of the fluid. For simplicity we will assume that the pressure distribution to be uniform on the liquid surface behind the front, but to vary in time: $p_1(r, t) = p_A(R)$, where $R = R(t)$ is the equation of motion of the front over the surface.

The simplest form of pressure distribution along the axis $Oz$ below the surface will be

$$p(0, z, t) = \frac{\partial}{\partial t} \int_0^{r_0} \frac{p_1(r, t') r dr}{\sqrt{r^2 + z^2}},$$ \hspace{1cm} (2.1)

where
\[ r_0^* = R \left( t - \frac{V r_0^* + z^2}{a} \right); \quad t' = t - \frac{V r_0^* + z^2}{a}. \]

We will assume that \( p_1(r,t) = p_A(R) = C/R^\alpha \), where \( C \) and \( \alpha \) are certain constants, and \( R(t) = Bt^\theta \) for the law of motion of the front. Then we obtain the pressure distribution along \( O\zeta \) in the form:

\[ p(0,z,t) = \frac{C}{aB^3} \left[ \frac{z + r_0^*}{V r_0^* + z^2} - \frac{1}{a} \right]. \]  \( (2,2) \)

From the conservation equations it follows that \( \beta = 2/\sqrt{(2 + \alpha)} \) on the front at the point \( A \). The greatest interest centers about the behavior of the solution when \( z \to at \). When this happens it is clear that \( r_0^* \to 0 \).

Evaluating the indeterminate form in \( (2,2) \) it is easy to convince ourselves that, for example, with \( \alpha = 3 \), (the pressure at \( z = at \)) (at the front of the sound wave) becomes negatively infinite. Thus in those cases where \( p_1(r,t) \) has a singularity close to the front of the sound wave as \( t \to 0 \), the linear theory ceases to apply.

Calculations show that even when this singularity is absent, negative pressures are possible below the surface. But this appears to have a definite physical meaning.

Calculation also shows that zones of strong rarefaction occur when the pressure on the free surface drops sharply with time, and that they are distributed between the free surface of the liquid and regions of higher pressure.
close to the sound-wave front. This result is somewhat unexpected if it is kept in mind that when $P_1$ and $R' = V_0$ are constant in time, the pressure is essentially monotonic and positive; here, for example, when $V_0 = a$ the pressure changes according to the linear equation:

$$\frac{p(0, z, t)}{p_i} = 1 - \frac{z}{a}.$$  \hspace{1cm} (2,3)

In order to illustrate the above considerations, we will investigate the following example. Let the pressure distribution on the surface behind the front be constant while the pressure on the front changes according to the law illustrated in Fig. 3.

Here $t'$ is some instant of time. Let the pressure $p_0$ correspond to a front velocity $V_0 = a$ and the pressure $p_2$ to $V_2 < a$. 

--- 11 ---
In accordance with (2.1) and the law adopted for \( p_1(r,t) \), there results:

\[
p(0, z, t) = -a \frac{\partial}{\partial t} \int_{t-\frac{z}{a}}^{t} \frac{p_A[R(t')] dt'}{\sqrt{\frac{r_0^2}{a^2} + z^2}}.
\]  (2.4)

Clearly for \( t < \bar{t} \) we have \( t' \) that much smaller than \( t \) and all integration intervals in (2.4) lie to the left of \( t' = \bar{t} \) in Fig. 3. For such values of \( t \) Eq. (2.3) holds.

We will investigate two different cases for \( t < \bar{t} \):

1) \( z > a(t-\bar{t}) \); here \( t' < \bar{t} \) also and Eq. (2.3) holds;

2) \( z < a(t-\bar{t}) \); here \( t-z/a > t \), but for some interval on the \( z \)-axis we have \( t - \sqrt{\frac{r_0^2}{a^2} + z^2} < \bar{t} \).

Then (2.4) takes the form:

\[
p(0, z, t) = -a \frac{\partial}{\partial z} \int_{t}^{t} p_0 dt' - a \frac{\partial}{\partial z} \int_{t-\frac{z}{a}}^{t} p_2 dt' = -p_0 \frac{z}{a} + p_2.
\]  (2.5)

At the point \( z = a(t-\bar{t}) \) there is a pressure discontinuity:

\[
p(0, z, t) = -p_0 + p_0 \frac{t}{t} + p_2.
\]

and we take \( \bar{t} \ll t \) and \( p_2 \ll p_0 \), then it is clear that \( p(0, z, t) = 0 \). Thus the step-function pressure distribution on the free surface produces a nonmonotonic pressure distribution differing from (2.3) below the surface, and
in certain cases produces zones of rarefaction.
