1. SCOPE

1.1 IDENTIFICATION

The Advanced Propagation Model (APM) Version 1.3.1 computer software configuration item (CSCI) calculates range-dependent electromagnetic (EM) system propagation loss within a heterogeneous atmospheric medium over variable terrain, where the radio-frequency index of refraction is allowed to vary both vertically and horizontally, also accounting for terrain and rough sea surface effects along the path of propagation.

1.2 SYSTEM OVERVIEW

The APM CSCI model will calculate propagation loss values as EM energy propagates through a laterally heterogeneous atmospheric medium where the index of refraction is allowed to vary both vertically and horizontally, also accounting for terrain effects along the path of propagation. Numerous Naval Integrated Tactical Environmental Subsystem (NITES) applications require EM-system propagation loss values. The required APM model described by this document may be applied to two such NITES applications, one of which displays propagation loss on a range versus height scale (commonly referred to as a coverage diagram) and one which displays propagation loss on a propagation loss versus range/height scale (commonly referred to as a loss diagram).

1.3 DOCUMENT OVERVIEW

This document specifies the functional requirements that are to be met by the APM CSCI. A discussion of the input software requirements is presented together with a general description of the internal structure of the APM CSCI as it relates to the CSCI’s capability.

2. REFERENCED DOCUMENTS

3. REQUIREMENTS

3.1 CSCI CAPABILITY REQUIREMENTS

The required APM CSCI propagation model is a range-dependent true hybrid model that uses the complementary strengths of both Ray Optics (RO) and Parabolic Equation (PE) techniques to calculate propagation loss both in range and altitude.

The atmospheric volume is divided into regions which lend themselves to the application of the various propagation loss calculation methods. Figure 1 illustrates these regions.

For antenna elevation angles above 5 degrees or for ranges less than approximately 2.5 kilometers (km), a flat-earth (FE) ray-optics model is used. In this region, only receiver height is corrected for average refraction and earth curvature.

Within the RO region (as defined by a limiting ray), propagation loss is calculated from the mutual interference between the direct-path and surface-reflected ray components using the refractivity profile at zero range. Full account is given to focusing or de-focusing along both direct and reflected ray paths and to the integrated optical path length difference between the two ray paths, to give precise phase difference, and, hence, accurate coherent sums for the computation of propagation loss.

Figure 1. APM calculation regions.
For the low-altitude region beyond the RO region, a PE approximation to the Helmholtz full wave equation is employed. The PE model allows for range-dependent refractivity profiles and variable terrain along the propagation path and uses a split step Fourier method for the solution of the PE. The PE model is run in the minimum region required to contain all terrain and trapping layer heights.

For the area beyond the RO region but above the PE region, an extended optics region (XO) is defined. Within the XO region, ray-optics methods which are initialized by the PE solution given below are used.

APM will run in three “execution” modes depending on environmental inputs. APM will use the FE, RO, XO, and PE models if the terrain profile is flat for the first 2.5 km and if the antenna height is less than or equal to 100 m. It will use only the XO and PE models if the terrain profile is not flat for the first 2.5 km and if the antenna height is less than or equal to 100 m. For applications in which the antenna height is greater than 100 meters, a combination of FE and PE methods are used. The FE model is used for all propagation angles greater than ±5° from the source and the PE model is used for angles less than ±5°. By default, APM will automatically choose which mode of operation it will use for a specified set of inputs. However, the ability to run only the PE model for any case is allowed by setting a logical flag upon input.

The APM CSCI allows for horizontal and vertical antenna polarization, finite conductivity based on user-specified ground composition and dielectric parameters, rough sea surface effects, and the complete range of EM system parameters and most antenna patterns required by NITES. APM also allows for gaseous absorption effects in all sub-models and computes troposcatter losses within the diffraction region and beyond.

The program flow of the required APM CSCI is illustrated Figure 2. Note that the APM CSCI is shown within the context of a calling CSCI application such as one that generates a coverage or loss diagram. The efficient implementation of the APM CSCI will have far reaching consequences upon the design of an application CSCI beyond those mentioned in Section 3.10. For example, Figure 2 shows checking for the existence of a previously created APM output file prior to the access of the APM CSCI. The application CSCI will have to consider if the atmospheric or terrain environment has changed since the APM output file was created or if any new height or range requirement is accommodated within the existing APM CSCI output file. Because these and many more considerations are beyond the scope of this document to describe, an application CSCI designer should work closely with the APM CSCI development agency in the implementation of the APM CSCI. Figure 3 through Figure 6 illustrate the program flow for the main compute software components (CSC), APMINIT CSC, APMSTEP CSC, XOINIT CSC, and XOSTEP CSC, respectively.

Initialize angle, height, range arrays for start of XO calculations

No

Deallocate all APM arrays (APMCLEAN SU)

Terrain case?

Yes

Perform 2-pass smoothing on angle array

No

Return to NITES CSCI

Figure 5. XOINIT CSC program flow.
The APM CSCI is divided into four main computer software components (CSC) and 47 additional software units (SUs). The name, purpose, and a general description of processing required for each SU follows.

### 3.1.1 Advanced Propagation Model Initialization (APMINIT) CSC

The purpose of the APMINIT CSC is to interface with various SUs for the complete initialization of the APM CSCI.

The atmospheric volume must be “covered” or resolved with a mesh of calculation points which will normally exceed the height/range resolution requirements of the particular application of the APM CSCI. Upon entering the APMINIT CSC, a range and height grid size per the APM CSCI output point is calculated from the number of APM outputs and the maximum CSCI range and height.

A TERINIT SU is referenced to examine the terrain profile. The minimum terrain height is determined, and then the entire terrain profile is adjusted by this height so that
all internal calculations are referenced to this height. This is done in order to minimize the required PE transform size.

User-specified environmental and system parameters are examined to determine if the APM CSCI will execute in a full hybrid mode, a partial hybrid mode, or PE-only mode.

A REFINIT SU is referenced to initialize the NITES CSCI specified modified refractivity and also to test for valid environment profiles. A PROFREF SU adjusts the environment profiles by the internal reference height, and a INTPROF SU defines the modified refractivity at all PE vertical mesh points.

If rough surface calculations are required (i.e., a non-zero wind speed is specified) a GETGRAZE SU is referenced to determine the grazing angles for the given refractivity profile. The grazing angles are then sorted and a GRAZE_INT SU is referenced to combine grazing angles computed by both methods (if necessary) and interpolate for subsequent use in rough surface calculations.

In order to automatically determine the maximum PE calculation angle, a GETTHMAX SU is referenced. This determines, via ray tracing, the minimum angle for which adequate coverage can be given with the specified terrain and environment profile. A FFTPAR SU is referenced to determine the Fast-Fourier transform (FFT) size for the calculated angle and to initialize data elements within the PE region which are dependent on the size of the FFT. The minimum size for the FFT is determined from the Nyquist criterion. There is also an option to activate only the PE algorithm within the APM CSCI, regardless of inputs. If this option is enabled, the PE maximum calculation angle is supplied by the calling CSCI.

If vertical polarization is specified, then additional calculations are performed in the starter solution using Kuttler and Dockery’s mixed transform method (Refs. 8, 9). In this case, a DIEINIT SU is used to initialize dielectric ground constants. For general ground types, the permittivity and conductivity are calculated as a function of frequency from curve fits to the permittivity and conductivity graphs shown in recommendations and reports of the International Radio Consulting Committee (Ref. 4).

A PE initialization SU (PEINIT) is referenced to initialize all variables and arrays associated with PE calculations. A XYINIT SU and an antenna pattern factor SU (ANTPAT) are referenced to generate a first solution to the PE. A FFT SU is referenced for data elements required in obtaining the PE’s starting solution.

If rough surface calculations are required, or if performing a finite-conducting boundary case, then a ALN_INIT SU is referenced to initialize field variables used in the mixed transform algorithm.
If running in a full hybrid mode, a FILLHT SU is referenced to determine the heights at each output range separating the FE, RO, and PE calculation regions. If running in a partial hybrid or PE-only mode, then the heights at each output range are determined, below which propagation loss/factor solutions are valid. No propagation loss/factor solutions are provided above these heights for those execution modes.

A TROPOINIT SU is referenced to initialize all variables and arrays associated with troposcatter calculations. This is referenced only if the user has enabled the $T_{ropo}$ flag.

Finally, a GASABS SU is referenced to initialize the attenuation parameter due to oxygen and water vapor absorption.

3.1.1.1 Allocate Arrays APM (ALLARRAY_APM) SU

The purpose of the ALLARRAY_APM SU is to allocate and initialize all dynamically dimensioned arrays associated with APM terrain, refractivity, troposcatter, and general variable arrays.

3.1.1.2 Allocate Array PE (ALLARRAY_PE) SU

The purpose of the ALLARRAY_PE SU is to allocate and initialize all dynamically dimensioned arrays associated with PE calculations.

3.1.1.3 Allocate Array RO (ALLARRAY_RO) SU

The purpose of the ALLARRAY_RO SU is to allocate and initialize all dynamically dimensioned arrays associated with RO calculations.

3.1.1.4 Allocate Array XORUF (ALLARRAY_XORUF) SU

The purpose of the ALLARRAY_XORUF SU is to allocate and initialize all dynamically dimensioned arrays associated with XO and rough surface calculations.

3.1.1.5 Alpha Impedance Initialization (ALN_INIT) SU

The purpose of the ALN_INIT SU is to initialize variables used in the discrete mixed Fourier transform (DMFT) algorithm for finite conductivity and/or rough surface calculations.

3.1.1.6 Antenna Pattern (ANTPAT) SU

The purpose of the ANTPAT SU is to calculate a normalized antenna gain (antenna pattern factor) for a specified antenna elevation angle.

From the antenna beam width, elevation angle (an angle for which the antenna pattern factor is desired) and the antenna radiation pattern type, an antenna factor is calculated.
3.1.1.7 Dielectric Initialization (DIEINIT) SU

The purpose of the DIEINIT SU is to determine the conductivity and relative permittivity as functions of frequency in MHz based on general ground composition types.

3.1.1.8 FFT Parameters (FFTPAR) SU

The purpose of the FFTPAR SU is to determine the required transform size based on the maximum PE propagation angle and the maximum height needed. If running in full or partial hybrid modes, the maximum height needed is the height necessary to encompass at least 20% above the maximum terrain peak along the path or the highest trapping layer specified in the environment profiles, whichever is greater. If running in a PE-only mode, the maximum height needed is the specified maximum output height. An error is returned if the computed transform size reaches $2^{30}$.

For computational efficiency reasons, an artificial upper boundary must be established for the PE solution. To prevent upward propagating energy from being “reflected” downward from this boundary and contaminating the PE solution, the PE solution field strength should be attenuated or “filtered” above a certain height to ensure that the field strength just below this boundary is reduced to zero.

The total number of vertical points for which a transformation will be computed is determined. This term is also referred to as the FFT size. The filtering boundary height is also determined.

3.1.1.9 Fill Height Arrays (FILLHT) SU

The purpose of the FILLHT SU is to calculate the effective earth radius for an initial launch angle of $5^\circ$ and to fill an array with height values at each output range of the limiting sub-model, depending on which mode is being used. If running in a full hybrid mode, the array contains height values at each output range separating the FE from the RO region. If running in other modes, the array contains those height values at each output range at which the initial launch angle has been traced to the ground or surface. For an execution mode in which PE and XO models are used, these height values represent the separating region where, above that height, valid loss is computed, and below that height, no loss is computed. This is done so only loss values that fall within a valid calculation region are output. For airborne applications in which a combination of PE and FE models are used, the array contains the height values at each range separating the FE and PE regions.

3.1.1.10 Gaseous Absorption (GASABS) SU

The purpose of the GASABS SU is to compute the specific attenuation based on air temperature and absolute humidity. This SU is based on CCIR (International Telecommunication Union, International Radio Consultative Committee, now the ITU-R) Recommendation 676-1, “Attenuation by Atmospheric Gases in the Frequency Range 1-350 GHz.”
3.1.1.11 Get Effective Earth Radius Factor (GET_K) SU

The purpose of the GET_K SU is to compute the effective earth radius factor and the effective earth radius. The computation is made for a launch angle of 5° if the SU is called from the APMINIT CSC. If called from the TROPOINIT SU, then the computation is made for a launch angle equal to the critical angle.

3.1.1.12 Get Alpha Impedance (GETALN) SU

The purpose of the GETALN SU is to compute the impedance term in the Leontovich boundary condition, and the complex index of refraction for finite conductivity, vertical polarization, and rough sea surface calculations. These formulas follow Kuttler and Dockery’s method (Ref. 9).

3.1.1.13 Get Grazing Angle (GETGRAZE) SU

The purpose of the GETGRAZE SU is to compute the grazing angles at each PE range step for subsequent use in rough sea surface calculations. The grazing angle computation is done using two methods. The first method uses ray trace by referencing a RDTRACE SU to compute grazing angles. The second is done by spectral estimation of the near-surface PE field. The near-surface PE field is computed by performing a “PE run” for a smooth surface, perfect conducting, horizontal polarization case at a fixed frequency (10 GHz) and fixed PE maximum calculation angle (4°).

3.1.1.14 Get Maximum Angle (GETTHMAX) SU

The purpose of the GETTHMAX SU is to perform an iterative ray trace to determine the minimum angle required (based on the reflected ray) in obtaining a PE solution. The determination of this angle will depend on the particular mode of execution. For the full and partial hybrid modes, a ray is traced up to a height that exceeds at least 20% above the maximum terrain peak along the path or the highest trapping layer specified in the environment profiles, whichever is greater. The maximum PE propagation angle is then determined from the local maximum angle of the traced ray.

3.1.1.15 Grazing Angle Interpolation (GRAZE_INT) SU

The purpose of the GRAZE_INT SU is to interpolate grazing angles at each PE range step based on angles computed from ray trace (takes precedence) and those computed from spectral estimation. These are used for subsequent rough surface calculations.

3.1.1.16 Interpolate Profile (INTPROF) SU

The purpose of the INTPROF SU is to perform a linear interpolation vertically with height on the refractivity profile. Interpolation is performed at each PE mesh height point.

3.1.1.17 PE Initialization (PEINIT) SU

The purpose of the PEINIT SU is to initialize all variables used in the PE model for subsequent calls to the PESTEP SU. The PE calculation height mesh and range step
size are determined. The free-space propagator term is computed at each PE angle, or p-space, mesh point using the wide-angle propagator. A filter, or attenuation function (frequently called “window”), is applied to the upper ¼ of the array corresponding to the highest ¼ of the maximum propagation angle. Next, the environmental phase term is computed at each PE height, or z-space, mesh point (if performing a smooth surface, refractive homogeneous case). A filter, or attenuation function (frequently called “window”), is applied to the upper ¼ of the mesh points corresponding to the highest ¼ of the calculation height domain. Finally, a XYINIT SU is referenced to initialize the PE starting field.

3.1.1.18 Profile Reference (PROFREF) SU

The purpose of the PROFREF SU is to adjust the current refractivity profile so that it is relative to a reference height. The reference height is initially the minimum height of the terrain profile. Upon subsequent calls from the PESTEP SU, the refractivity profile is adjusted by the local ground height at each PE range step.

3.1.1.19 RD Trace (RDTRACE) SU

The purpose of the RDTRACE SU is to perform ray traces of many rays launched within an angle of ±4°. All angles from rays striking the surface are then sorted and stored for subsequent interpolation in the GRAZE_INT SU.

3.1.1.20 Refractivity Initialization (REFINIT) SU

The purpose of the REFINIT SU is to check for valid environmental profile inputs and to initialize all refractivity arrays.

The environmental data is checked for a range-dependent profile and tested to determine if the range of the last profile entered is less than the maximum output range specified. If so, an integer error flag is returned and the SU exited, depending on the values of logical error flags set in the NITES CSCI itself.

The REFINIT SU also tests for valid refractivity level entries for each profile. If the last gradient in any profile is negative, it returns an integer error flag and the SU is exited. If no errors are detected, the REFINIT SU then extrapolates the environmental profiles vertically to 1000 km in height. Extrapolation is not performed horizontally from the last provided profile; rather, the last provided environment profile is duplicated at 10⁷ km in range. This duplication of profiles is done by the REFINITER SU. Finally, the REFINIT SU checks if an evaporation duct profile has been specified.

3.1.1.21 Remove Duplicate Refractivity Levels (REMDUP) SU

The purpose of the REMDUP SU is to remove any duplicate refractivity levels in the currently interpolated profile.
3.1.1.22 Terrain Initialization (TERINIT) SU

The purpose of the TERINIT SU is to examine and initialize terrain arrays for subsequent use in PE calculations. It tests for and determines a range increment if it is found that range/height points are provided in fixed range increments. The minimum terrain height is determined and the entire terrain profile is adjusted so all internal calculations are referenced to this height. This is done in order to maximize the PE transform calculation volume.

3.1.1.23 Trace to Output Range (TRACE_ROUT) SU

The purpose of the TRACE_ROUT SU is to trace a single ray, whose launch angle is specified by the calling routine, to each output range. The height of this ray is stored at each output range for subsequent proper indexing and accessing of the appropriate sub-models.

3.1.1.24 Troposcatter Initialization (TROPOINIT) SU

The purpose of the TROPOINIT SU is to initialize all variables and arrays needed for subsequent troposcatter calculations. The tangent range and tangent angle are determined from the source and from all receiver heights and stored in arrays.

3.1.1.25 Starter Field Initialization (XYINIT) SU

The purpose of the XYINIT SU is to calculate the complex PE solution at range zero.

Several constant terms which will be employed over the entire PE mesh are calculated. These are the angle difference between mesh points in p-space and a height-gain value at the source (transmitter).

For each point in the PE p-space mesh, the antenna pattern ANTPAT SU is referenced to obtain an antenna pattern factor for both a direct-path ray and a surface-reflected ray. The complex portions of the PE solution are then determined from the antenna pattern factors, elevation angle, and antenna height. The initial field assumes the source is over a perfectly conducting ground.

3.1.2 Advanced Propagation Model Step (APMSTEP) CSC

The purpose of the APMSTEP CSC is to advance the entire APM CSCI algorithm one output range step, referencing various SUs to calculate the propagation loss at the current output range. At this current range, APM calculations will be made within the vertical (up to the maximum PE height region) by accessing the appropriate region’s SUs.

The current output range is determined. The PESTEP SU is referenced to obtain the PE portion of the propagation loss at this new range.
For an airborne application, the AIRBORNE SU is referenced to obtain the FE portion of the propagation loss above and below the PE maximum propagation angle.

If running in full hybrid mode, then based upon a height array index used within the FE region, a determination is made for the necessity to include FE propagation calculations. If so, the FEM SU is referenced to obtain the FE portion of the propagation loss. If a FE calculation is made, the maximum height index for the RO region is adjusted (with the minimum height index corresponding to the maximum height index of the PE region), and the ROM SU is referenced to obtain the RO portion of the propagation loss at the current range. FE and RO propagation loss will be computed only up to the range at which XO calculations will be performed.

If running in a partial hybrid (PE + XO) mode, then only the PESTEP SU will be referenced to obtain the PE portion of the propagation loss at this new range.

Finally, absorption loss is computed for the current range and added to the propagation loss at all heights.

3.1.2.1 Airborne Hybrid Model (AIRBORNE) SU

The purpose of the AIRBORNE SU is to determine propagation loss based on flat-earth calculations for the direct ray path only for regions above and below the PE maximum propagation angle.

3.1.2.2 Calculate Propagation Loss (CALCLOS) SU

The purpose of the CALCLOS SU is to determine the propagation loss from the complex PE field at each output height point at the current output range.

The local ground height at the current output range is determined. All propagation loss/factor values at output height points up to the local ground height are then set to -999. The first valid loss point is determined corresponding to the first output height point above the ground height. Next, the last valid loss point is determined based on the smaller of the maximum output height or the height traced along the maximum PE propagation angle to the current output range.

From the height of the first valid loss point to the height of the last valid loss point, the GETPFAC SU is referenced to obtain the propagation factor in dB (field strength relative to free space) at all corresponding output heights at the previous and current PE ranges. Then, for each valid output height, horizontal interpolation in range is performed to obtain the propagation factor at the current output range. From the propagation factor and the free-space loss, the propagation loss at each valid output height is determined, with the propagation loss/factor set to -1000 for all output height points above the last valid output height but less than the maximum output height.
If running in full or partial hybrid modes, the propagation factor at the top of the PE region is determined at every output range and stored in an array for future reference in XO calculations. If troposcatter calculations are desired, the TROPOSCAT SU is referenced with the results added to the propagation loss/factor array. Absorption loss is computed for the current range and added to the propagation loss at all heights. All loss/factor values returned to the NITES CSCI at this point are in centibels (10 cB = 1 dB).

3.1.2.3 DoShift SU

The purpose of the DOSHIFT SU is to shift the complex PE field by the number of bins, or PE mesh heights corresponding to the local ground height.

Upon entering, the number of bins to be shifted are determined. The PE solution is then shifted downward if the local ground is currently at a positive slope, and upward if the local ground is at a negative slope.

3.1.2.4 Discrete Sine/Cosine Fast-Fourier Transform (DRST) SU

A function with a common period, such as a solution to the wave equation, may be represented by a series consisting of sines and cosines. This representation is known as a Fourier series. An analytical transformation of this function, known as a Fourier transform, may be used to obtain a solution for the function.

The solution to the PE approximation to Maxwell’s wave equation is to be obtained by using such a Fourier transformation function. The APM CSCI requires the real-valued sine and cosine transformations in which the real and imaginary parts of the PE equation are transformed separately. A Fourier transformation for possible use with the APM CSCI is described by Bergland (Ref. 1) and Cooley, Lewis, and Welsh (Ref. 2).

3.1.2.5 Flat-Earth Model (FEM) SU

The purpose of the FEM SU is to compute propagation loss at a specified range based upon flat-earth approximations. Receiver heights are corrected for earth curvature and average refraction based on twice the effective earth radius computed in the GET_K SU. The following steps are performed for each APM output height.

1. The path lengths and elevation angles for both the direct-path and surface-reflected path, along with the grazing angle, are computed from simple right triangle calculations. Using the two elevation angles, the ANTPAT SU is referenced to obtain an antenna pattern factor for each angle. Using the grazing angle, the GETREFCOEF SU is referenced to obtain the magnitude and phase lag of the surface reflection coefficient.

2. From the path length difference, the phase lag of the surface reflected ray, and the wave number, a total phase lag is determined. Using the total phase lag, the magnitude of the surface reflection coefficient and the two antenna pattern factors, the
two ray components are coherently summed to obtain a propagation factor. The propagation factor, together with the free-space propagation loss and path length difference of the direct-path ray are used to compute the propagation loss.

3.1.2.6 Fast-Fourier Transform (FFT) SU
The purpose of the FFT SU is to separate the real and imaginary components of the complex PE field into two real arrays and then reference the DRST SU which transforms each portion of the PE solution.

3.1.2.7 Free-Space Range Step (FRSTP) SU
The purpose of the FRSTP SU is to propagate the complex PE solution field in free space by one range step.

The PE field is transformed to p-space and then multiplied by the free-space propagator. Before exiting, the PE field is transformed back to z-space. Both transforms are performed using a FFT SU.

3.1.2.8 FZLIM SU
The purpose of the FZLIM SU is to determine both the propagation factor (in dB) and the outgoing propagation angle at the top of the PE calculation region. These values, along with the corresponding PE range, are stored for future reference by the XOINIT SU.

The GETPFAC SU is referenced to determine the propagation factor at the last height mesh point in the valid part of the PE region. The propagation factor, along with the range and the local ray angle (determined from the ray traced separating the RO and PE regions), is stored if this is the first call to the FZLIM SU. The SPECEST SU is then referenced to determine the outgoing propagation angle. Depending on the change of angles from one range step to the next, the calculated outgoing angle will be limited. The storage array counter is incremented and the outgoing angle stored.

Before exiting, the SAVEPRO SU is referenced to store the refractivity profiles from the top of the PE region to the maximum specified coverage height.

3.1.2.9 Get Propagation Factor (GETPFAC) SU
The purpose of the GETPFAC SU is to determine the propagation factor at the specified height in dB.

A vertical interpolation with height on the PE solution field is performed to obtain the magnitude of the field at the desired output height point. An additional calculation is made and the propagation factor is then returned in dB.
3.1.2.10 Get Reflection Coefficient (GETREFCOEF) SU
The purpose of the GETREFCOEF SU is to calculate the complex surface reflection coefficient, along with the magnitude and phase angle.

The complex reflection coefficient is computed from a specified grazing angle and is based on the Fresnel reflection coefficient equations for vertical and horizontal polarization. The magnitude and phase angle are determined from the complex reflection coefficient. If rough surface calculations are required, the smooth surface reflection coefficient is then modified by the Miller-Brown rough surface reduction factor, which is a function of wind speed and grazing angle.

3.1.2.11 Mixed Fourier Transform (MIXEDFT) SU
The purpose of the MIXEDFT SU is to propagate the PE field in free space one PE range step, applying the Leontovich boundary condition, using the mixed Fourier transform as outlined by Kuttler and Dockery (Ref. 9). For finite conducting boundaries (i.e., if vertical polarization is specified or rough surface calculations are required) and the frequency is less than 400 MHz, the central difference form of the DMFT is used. If the frequency is greater than 400 MHz, the backward difference form of the DMFT is used.

3.1.2.12 Parabolic Equation Step (PESTEP) SU
The purpose of the PESTEP SU is to advance the PE solution one output range step, referencing various SUs to calculate the propagation loss at the current output range.

The next output range is determined and an iterative loop begun to advance the PE solution such that for the current PE range, a PE solution is calculated from the solution at the previous PE range. This procedure is repeated until the output range is reached.

At each PE range step, the local ground height is determined and the PE field is “shifted” by the number of bins, or PE mesh height points, corresponding to the local ground height. This is performed in the DOSHIFT SU.

If the APM CSCI is being used in a range-dependent mode, that is, more than one profile has been input, or a terrain profile is specified, the REFINTER SU is referenced to compute a new modified refractive index profile adjusted by the local ground height at the current range. A new environmental phase term is computed using this new refractivity profile.

If using vertical polarization and the current ground type has changed from the previous one, or rough surface calculations are required, a GETALN SU is referenced to determine the impedance term and all associated variables used for the mixed transform calculations.
If rough surface calculations are required, or if using vertical polarization, then a MIXEDFT SU is referenced; otherwise, a FRSTP SU is referenced to advance the PE solution one range step in free space. The environmental phase term is then applied to obtain the new final PE solution at the current range. Once all calculations are made to determine the PE field at the current PE range, the FZLIM SU is referenced to determine and store the outgoing propagation factor and propagation angle at the top of the PE region. The FZLIM SU is only referenced if running in full or partial hybrid modes. Finally, a CALCLS SU is referenced to obtain the propagation loss/factor at the desired output heights at the current output range.

3.1.2.13 Ray Trace (RAYTRACE) SU

Using standard ray trace techniques, a ray is traced from a starting height and range with a specified starting elevation angle to a termination range. As the ray is being traced, an optical path length difference and a derivative of range with respect to elevation angle are being continuously computed. If the ray should reflect from the surface, a grazing angle is determined. Upon reaching the termination range, a terminal elevation angle is determined along with a termination height.

3.1.2.14 Refractivity Interpolation (REFINTER) SU

The purpose of the REFINTER SU is to interpolate both horizontally and vertically on the modified refractivity profiles. Profiles are then adjusted so they are relative to the local ground height.

If range-dependent refractive profiles have been specified, horizontal interpolation to the current PE range is performed between the two neighboring profiles. A REMDUP SU is referenced to remove duplicate refractivity levels, and the PROFREF SU is then referenced to adjust the new profile relative to the internal reference height corresponding to the minimum height of the terrain profile. The PROFREF SU is referenced once more to adjust the profile relative to the local ground height, and upon exit from the PROFREF SU, the INTPROF SU is referenced to interpolate vertically on the refractivity profile at each PE mesh height point.

3.1.2.15 Ray Optics Calculation (ROCALC SU)

The purpose of the RO CALC SU is to compute the RO components needed in the calculation of propagation loss at a specified range and height within the RO region. These components are the amplitudes for a direct-path and surface-reflected ray, and the total phase lag angle between the direct-path and surface-reflected rays.

A test is made to determine if this is the first RO calculation. If an initial calculation is needed, the height, range, and elevation angle array indices are set to initial conditions. If not, the array indices are incremented from the previous RO calculation.

The following steps are performed for each series of vertical grid points, in a manner that ensures that RO calculations have been performed at ranges that span the
current range of interest. The vertical grid points are taken in order beginning with the one with greatest height.

1. Using a Newton iteration method with a varying elevation angle, the RAYTRACE SU is referenced to find a direct-path ray and a surface-reflected ray originating at the transmitter height and terminating at the same grid point. Should a direct or reflected ray not be found to satisfy the condition, or should the computed grazing angle exceed the grazing angle limit, the height array index is adjusted to redefine the lower boundary of the RO region. Should the ray trace conditions be satisfied, the RAYTRACE SU will provide a terminal elevation angle, a derivative of range with respect to elevation angle, a path length, and for the surface-reflected ray, a grazing angle.

2. Using the final direct-path ray and surface-reflected ray elevation angles obtained from the Newton iteration method, the ANTPAT SU is referenced to obtain an antenna pattern factor for each angle. The GETREFCOEF SU is referenced to obtain the amplitude and phase lag angle of the surface reflection coefficient.

3. Using the antenna pattern factors, path length differences, and surface-reflection coefficients, the necessary RO components defined in the first paragraph above are calculated.

3.1.2.16 Ray Optics Loss (ROLOSS) SU

The purpose of the ROLOSS SU is to calculate propagation factor and loss values at all valid RO heights at a specified range based upon the components of magnitude for a direct-path and surface-reflected ray and the total phase lag angle between the two rays as determined by the ROCALC SU.

For purposes of computational efficiency, an interpolation from the magnitude and total phase lag arrays, established by the ROCALC SU, is made to obtain these three quantities at each APM vertical output mesh point within the RO region.

From the interpolated phase lag and ray amplitudes, a propagation factor is calculated which is used, in turn, with the free-space loss to obtain a propagation loss at each vertical APM output point. Absorption loss is computed for the current range and added to the propagation loss at all heights.

3.1.2.17 Save Profile (SAVEPRO) SU

The purpose of the SAVEPRO SU is to store refractivity profiles at each PE range step from the top of the PE region to the maximum user-specified height and redefined.
The refractivity height level just exceeding the PE region height limit is determined. From this level upward, all heights, M-units, and gradients are stored.

3.1.2.18 Spectral Estimation (SPECEST) SU

The purpose of the SPECEST SU is to determine the outward propagation angle at the top of the PE calculation region or the grazing angle at the lower part of the PE region based on spectral estimation. The outward propagation angle is used for XO calculations and the grazing angle is used for rough surface calculations.

The upper 8 (if running smooth surface case) or 16 (if running terrain case) bins of the complex PE field at the current PE range are separated into their real and imaginary components. The upper ¼ of this portion of the field is then filtered and zero-padded to 256 points. It is then transformed to its spectral components via a reference to the DRST SU. The amplitudes of the spectral field are then determined and a 3-point average is performed. The peak of the 256-point field is found and the outgoing propagation angle is determined from the peak value.

3.1.2.19 Troposcatter (TROPOSCAT) SU

The purpose of the TROPOSCAT SU is to determine the loss due to troposcatter and to compute the appropriate loss from troposcatter and propagation loss for large receiver ranges.

The current output range is updated and the tangent angle from the source to the current output range is initialized. For all output receiver heights at the current output range, the following procedure is performed.

1. If the current output range is less than the minimum diffraction field range for a particular receiver height, then the SU is exited and no troposcatter loss is computed.

2. The tangent angle from the receiver height is determined.

3. The common volume scattering angle is determined and calculations are performed to obtain the loss due to troposcatter.

4. Troposcatter loss is compared to propagation loss. If the difference between the propagation loss and troposcatter loss is less than 18 dB, then the corresponding power levels of the two loss values are added. If the difference is greater than 18 dB, then the lesser of the two losses is used.

3.1.3 Extended Optics Initialization (XOINIT) CSC

The purpose of the XOINIT SU is to initialize the range, height, and angle arrays in preparation for the XOSTEP CSC.
Upon entering, if XO calculations are not required, the APMCLEAN SU is referenced to deallocate all arrays used for the current application, then the CSC is exited.

If XO calculations are required, all arrays used for XO calculations are allocated and initialized to 0. The ranges and angles previously stored from referencing the FZLIM SU are now used to initialize the range and angle arrays for XO calculations. A 10-point smoothing average on the angle array is performed twice via reference to the MEANFILT SU. Upon exiting, the height array and initial height index for start of XO calculations are initialized.

### 3.1.3.1 Advanced Propagation Model Clean (APMCLEAN) SU
The purpose of the APMCLEAN CSC is to deallocate all dynamically dimensioned arrays used in one complete run of APM calculations.

### 3.1.3.2 Mean Filter (MEANFILT) SU
The purpose of the MEANFILT SU is to perform an n-point average smoothing on any array passed to it.

### 3.1.4 Extended Optics Step (XOSTEP) CSC
The purpose of the XOSTEP CSC is to advance the APM CSCI algorithm one output range step from the top of the PE calculation region to the maximum output height specified, referencing various SUs to calculate the propagation loss and factor at the current output range.

Upon entering the XOSTEP CSC, the current output range is determined. The EXTO SU is referenced to obtain the XO portion of the propagation loss and factor at this new range.

If running in full hybrid mode, based upon a height array index used within the FE region, determine if it’s necessary to include FE propagation calculations. If necessary, the FEM SU is referenced to obtain the FE portion of the propagation loss and factor. If a FE calculation is made, the maximum height index for the RO region is adjusted (with the minimum height index corresponding to the maximum height index of the PE region), and the ROLOSS SU is referenced to obtain the RO portion of the propagation loss and factor at the current range.

If running in partial hybrid mode, then only the EXTO SU is referenced to obtain the XO portion of the propagation loss and factor at this new range. The maximum height will correspond to the maximum user-specified coverage height.

Finally, the APMCLEAN SU is referenced to deallocate all allocated arrays used throughout the run.
3.1.4.1 Extended Optics (EXTO) SU

The purpose of the EXTO SU is to calculate propagation loss and factor, based on extended optics techniques, at the current output range.

Upon entering, array indices for the current range, height, and angle arrays are initialized. A ray trace is then performed for all rays from the last output range to the current output range. The current heights are then sorted, along with their corresponding propagation factors. The propagation loss is then determined at each output receiver height by interpolation on the terminal heights of the traced rays.

Upon exiting, a reference to the TROPOSCAT SU provides any troposcatter losses and is added to the loss array. Absorption loss is also added to the propagation loss at all heights.

3.2 CSCI EXTERNAL INTERFACE REQUIREMENTS

The APM CSCI is accessed, through the APMINIT CSC, by a subroutine call from the NITES CSCI which should provide, as global data elements, the values specified in Table 1 through Table 4.

The APM CSCI external data elements, i.e., those data which must be provided by the calling NITES CSCI prior to the APM CSCI execution may be divided into four classifications. The first is external data related to the atmospheric environment, specified within Table 1; the second is data related to the EM system, specified within Table 2; the third is data related to the implementation of the APM CSCI by the NITES CSCI, specified within Table 3; and the fourth is data related to the terrain information, specified within Table 4. Each table lists the type, units, and bounds of each data element. Table 5 specifies the output data of the APM CSCI model.
Table 1. APM CSCI environmental data element requirements.

\(^a\)Couplets of height and modified refractivity associated with that height are referred to within this document as a refractivity profile.

\(^b\)All heights in the refractivity profile must be steadily increasing.

\(^c\)The CCIR gaseous absorption model implemented within APM provides a ±15% accuracy for absolute humidity and surface air temperature within these bounds. While values beyond these limits are allowed within APM, it should be noted this may result in less accurate attenuation rates calculated.

### 3.3 CSCI INTERNAL INTERFACE REQUIREMENTS

Section 3.1 shows the relationship between the APM CSCI and its four CSCs: APMINIT, APMSTEP, XOINIT, and XOSTEP. The required internal interface between these four CSCs and the APM CSCI is left to the designer. However, Table 7 should be used as a guide to the required internal interfaces in the CSCI.

### 3.4 CSCI INTERNAL DATA REQUIREMENTS

The APM CSCI takes full advantage of Fortran 90 features, utilizing allocatable arrays for all internal and input arrays. This requires the NITES CSCI designer to correctly allocate and initialize all arrays necessary for input to the APM CSCI.

Due to the computational intensity of the APM CSCI, it may not be necessary or desirable to use the extreme capability of the APM CSCI for all applications. The variables \(n_{\text{rout}}\) and \(n_{\text{zout}}\) refer to the desired number of range and height output points for any one particular application, and will be specified when the APMINIT CSC is called.

One of the parameters returned to the NITES application from the APMINIT CSC is \(i_{\text{error}}\). This is to allow for greater flexibility in how input data is handled within the NITES application.

Table 6 lists all possible errors that can be returned.
Table 6. APMINIT SU returned error definitions.

</tbody>
</table>

The logical variables $lerr6$ and $lerr12$, when set to ‘.false.’, allow the NITES application to bypass their associated errors as these are not critical to the operation of the APM CSCI.

The APM CSCI provides propagation loss and propagation factor for all heights and ranges when running in a full hybrid mode. When running in a partial hybrid mode, it provides propagation loss and factor for all heights, but not necessarily for all angles. Refer to Section 3.1 for environmental conditions under which each execution mode is automatically selected.

Absorption by atmospheric gases (oxygen and water vapor) may be important to some applications of the APM CSCI and is controlled by specifying a non-zero value for the absolute humidity, $\text{abs}_{\text{hum}}$, and the surface air temperature, $t_{\text{air}}$; or likewise, specifying a non-zero value for the gaseous absorption attenuation rate, $\gamma_a$. 

A particular application of the APM CSCI may or may not require the consideration of troposcatter effects within the propagation loss/factor calculations. For example, a radar evaluation most likely would not be influenced by troposcatter; while an ESM evaluation would. APM has the feature of including or not including the troposcatter calculation by setting a logical flag called $T_{\text{ropo}}$. Setting this flag to `.false.` would omit the calculation. Setting this flag to `.true.` would include the calculation. For the APM CSCI implementation within the NITES coverage and loss diagram applications, $T_{\text{ropo}}$ must be set to `.true.` so as to include the calculation.

APM also has the added capability to account for rough sea surface effects. Specifying a wind speed and a corresponding range will produce forward scatter results based on the Philips ocean-wave model for the rms wave height and the Miller-Brown reflection coefficient reduction factor. The capability also exists to allow variable wind speeds with range (Ref. 19).

APM by default will run in an “automatic” mode which, depending upon user-specified inputs, will choose the appropriate sub-models to use for a particular application. However, by setting the logical flag $PE_{\text{flag}}$ to `.true.` this will force APM to use only the PE sub-model for a particular NITES application. By default, this flag is set to `.false.`. If this flag is `.true.` then the visible portion of the maximum PE propagation angle, $th_{\text{max}}$, (i.e., the maximum propagation angle the PE algorithm will accommodate in the field calculations) and the parameter, $r_{\text{mult}}$, must be specified. By default, $r_{\text{mult}}$ is equal to 1; however $th_{\text{max}}$ does not have a default value and must be explicitly defined. The parameter $r_{\text{mult}}$ is a range step multiplier, allowing the user to vary the PE range step from the default calculated.

Use this option with caution as you must have some basic knowledge of PE algorithms and how they work to input proper combinations of maximum calculation angles and range steps for a given frequency. When using this option, most error checking is bypassed and parameter limits can be over-ridden. Erroneous field values may result if a poorly chosen combination of $th_{\text{max}}$ and $r_{\text{mult}}$ are used.

3.5 ADAPTATION REQUIREMENTS

3.5.1 Environmental Radio Refractivity Field Data Elements

The radio-refractivity field, i.e., the profiles of M-units versus height, must consist of vertical piece-wise linear profiles specified by couplets of height in meters with respect to mean sea level and modified refractivity (M-units) at multiple arbitrary ranges. All vertical profiles must contain the same number of vertical data points, and be specified such that each numbered data point corresponds to like-numbered points (i.e., features) in the other profiles. The first numbered data point of each profile must correspond to a height of zero mean sea level and the last numbered data point must correspond to a
height such that the modified refractivity for all greater heights is well represented by extrapolation using the two highest profile points specified.

With the inclusion of terrain and allowing the terrain profile to fall below mean sea level, refractivity profiles can also be provided in which the first level is less than 0 (or below mean sea level). For a terrain profile that falls below mean sea level at some point, the assumption is that the minimum height may be less than the first height in any refractivity profile specified. Therefore, an extrapolation flag, \( i_{\text{extra}} \), must be specified to indicate how the APM CSCI should extrapolate from the first refractivity level to the minimum height along the terrain profile. Setting \( i_{\text{extra}} \) to 0 will cause the APM CSCI to extrapolate to the minimum height using a standard atmosphere gradient; setting \( i_{\text{extra}} \) to 1 will cause the APM CSCI to extrapolate to the minimum height using the gradient determined from the first two levels of the refractivity profile.

Within each profile, each numbered data point must correspond to a height greater than or equal to the height of the previous data point. Note that this requirement allows for a profile containing redundant data points. Note also that all significant features of the refractivity profiles must be specified, even if they are above the maximum output height specified for a particular application of APM.

The NITES CSCI application designer and the NITES operator share responsibility for determining appropriate environmental inputs. For example, a loss diagram may be used to consider a surface-to-surface radar detection problem. Since the operator is interested in surface-to-surface, he may truncate the profile assuming that effects from elevated ducting conditions are negligible. It may be, however, that the elevated duct does indeed produce a significant effect. The operator should ensure therefore, that the maximum height of the profile allows for the inclusion of all significant refractive features.

This specification allows a complicated refractivity field to be described with a minimum of data points. For example, a field in which a single trapping layer linearly descends with increasing range can be described with just two profiles containing only four data points each, frame (a) of Figure 7. In the same manner, other evolutions of refractive layers may be described. Frames (b) and (c) of Figure 7 show two possible scenarios for the development of a trapping layer. The scenario of choice is the one which is consistent with the true thermodynamical and hydrological layering of the atmosphere.
Two external implementation data variables applicable to both the NITES operator and to the calling application designer are $r_{\text{max}}$, the maximum APM CSCI output range, and $h_{\text{max}}$, the maximum APM CSCI output height. These two parameters are required by the APM CSCI to determine the horizontal and vertical resolution, respectively, for internal range and height calculations based on the current values of $n_{\text{rout}}$ and $n_{\text{zout}}$. Any value of $r_{\text{max}}$ and $h_{\text{max}}$ is allowed for the convenience of the NITES operator and the calling application designer, provided $r_{\text{max}} \geq 5$ km, and $h_{\text{max}} \geq 100$ m. For example, the NITES operator may desire a coverage diagram which extends to a range of 500 kilometers (km). In addition to accommodating the desires of the operator, specification of such a convenient maximum range eases the burden for the application designer in determining incremental tick marks for the horizontal axis of the display.

Figure 7. Idealized M-unit profiles (solid) and lines of interpolation (dashed).
Provided the value of the parameter \textit{lerr12} is set to ‘.false.’, if the furthest environment profile range is less than \( r_{\text{max}} \), the APM CSCI will automatically create an environment profile at \( r_{\text{max}} \) equal to the last profile specified, making the environment homogeneous from the range of the last profile specified to \( r_{\text{max}} \). For example, a profile is input with an accompanying range of 450 km. If the NITES operator chooses an \( r_{\text{max}} \) of 500 km, the APM CSCI will continue propagation loss/factor calculations to 500 km, keeping the refractivity environment homogeneous from 450 km to 500 km.

If \textit{lerr12} is set to ‘.true.’ and the furthest environment profile range is less than \( r_{\text{max}} \), then an error will be returned in \( i_{\text{error}} \) from the APMINIT CSC. This is to allow the NITES CSCI application designer greater flexibility in how environment data is handled.

### 3.5.2 Terrain Profile Data Element

The terrain profile must consist of linear piece-wise segments specified in terms of range/height pairs. All range values must be increasing, and the first terrain height value must be at range zero. General ground composition types can be specified (Table 4), along with corresponding ranges over which the ground type is to be applied. If ground type “User Defined” is specified (\( igrnd_i = 7 \)), then numeric values of relative permittivity and conductivity must be given. If horizontal antenna polarization is specified, and if running a smooth surface case, the APM CSCI will assume perfect conductivity for the entire terrain profile and will ignore any information regarding ground composition. If vertical antenna polarization is specified, or if performing rough surface calculations, then information regarding ground composition must also be specified. If wind speed has been provided, then rough surface calculations will also be performed.

The maximum height, \( h_{\text{max}} \), must always be greater than the minimum height, \( h_{\text{min}} \), by at least 100 meters. Also, a value of \( h_{\text{max}} \) must be given such that it is larger than the maximum elevation height along a specified terrain profile.

Provided \textit{lerr6} is set to ‘.false.’, if the furthest range point in the terrain profile is less than \( r_{\text{max}} \), the APM CSCI will automatically create a height/range pair as part of the terrain profile at \( r_{\text{max}} \) with elevation height equal to the last height specified in the profile, making the terrain profile flat from the range of the last profile point specified to \( r_{\text{max}} \). For example, a terrain profile is input where the last height/range pair is 50 meters in height with an accompanying range of 95 km. If the NITES operator chooses an \( r_{\text{max}} \) of 100 km, the APM CSCI will continue propagation loss/factor calculations to 100 km, keeping the terrain profile flat from 95 km to 100 km with an elevation height of 50 m.

If \textit{lerr6} is set to ‘.true.’ and the furthest range point is less than \( r_{\text{max}} \), then an error is returned in \( i_{\text{error}} \) from the APMINIT SU. This is to allow the NITES CSCI application designer greater flexibility in how terrain data is handled.
3.6 SECURITY AND PRIVACY REQUIREMENTS

The security and privacy requirements are the same as those required by the target employing NITES CSCI.

3.7 CSCI ENVIRONMENTAL REQUIREMENTS

The APM CSCI must be able to operate in the same hardware and software environments that the target employing NITES CSCI operates.

3.8 COMPUTER RESOURCE REQUIREMENTS

Section 3.1.2.4 describes requirements for a Discrete Sine/Cosine Fast-Fourier Transform (DRST) SU. However, other sine FFT routines are available in the commercial market, and such a sine FFT may already be available within another NITES CSCI. The selection of which FFT is ultimately used by APM CSCI is left to the application designer as every sine FFT will have hardware and/or software performance impacts.

3.9 SOFTWARE QUALITY FACTORS

The primary required quality factors can be divided into the three categories - design, performance, and adaptation.

The quality factors for the design category should include correctness, maintainability, and verifiability. Correctness describes the extent to which the APM CSCI conforms to its requirements and is to be determined from the criteria – completeness, consistency, and/or traceability. Maintainability specifies the effort required to locate and fix an error in the APM CSCI. Maintainability is to be determined from the criteria – consistency, modularity, self-descriptiveness (self-documentation), and/or simplicity. Verifiability characterizes the effort required to test the APM CSCI to ensure that it performs its intended function. Verifiability is to be determined from the criteria – modularity, self-descriptiveness, and/or simplicity.

The quality factor for performance category is reliability, which depicts the confidence that can be placed in the APM CSCI calculations. Reliability is to be determined from the criteria – accuracy, anomaly management, auditability, consistency, and/or simplicity.

The quality factors for the adaptation category are portability and reusability. Portability determines how easy it is to transport the APM CSCI from one hardware
and/or software environment to another. Portability is to be determined from the criteria – application independence, modularity, and/or self-descriptiveness. Reusability illustrates how easy it is to convert the APM CSCI (or parts of the CSCI) for use in another application. Reusability is to be determined from the criteria – application independence, document accessibility, functional scope, generality, hardware independence, modularity, simplicity, self-descriptiveness, and/or system clarity.

Section A.A.1 defines the software quality criteria.

Only the software quality criteria completeness, consistency, and traceability can be analyzed. Their calculation is described in Section A.2. The other criteria have to be determined by either demonstration, test, or inspection.

### 3.10 DESIGN AND IMPLEMENTATION CONSTRAINTS

#### 3.10.1 Implementation and Application Considerations

The calling NITES CSCI application will determine the employment of the APM CSCI. However, the intensive computational nature of the APM CSCI must be taken into consideration when designing an efficient calling application. For this reason, the APM CSCI should be designed with flexibility for various hardware suites and computer resource management considerations. As stated in Section 1, this APM CSCI applies only to a coverage and loss diagram application. The following highly recommended guidelines are provided to aid in the design of a coverage or loss diagram application which will most efficiently employ the APM CSCI.

The APM CSCI propagation loss calculations are independent of any target or receiver considerations; therefore, for any EM emitter, one execution of the APM CSCI may be used to create both a coverage diagram and a loss diagram. Since both execution time and computer memory allocation should be a consideration when employing this model, it is most efficient and appropriate to execute the APM CSCI for a particular EM system/environmental/terrain combination before executing any application. The output of the APM CSCI would be stored in a file which would be accessed by multiple applications.

For example, the NITES operator may desire a coverage diagram for one particular radar system. At the beginning of the coverage diagram application, a check would be made for the existence of a previously created APM CSCI output file appropriate for the EM system, environmental, and terrain conditions. If such a file exists, the propagation loss values would be read from the file and used to create the coverage diagram. If the file does not exist, the APM CSCI would be executed to create one. As the APM CSCI is executing, its output could be routed simultaneously to a graphics display device and a file. This file could then be used in the loss diagram application should the operator also choose it. Two distinct applications, therefore, are
achieved with only one execution of the APM CSCI. Additionally, should the operator desire an individual coverage diagram for each of multiple targets, or a single coverage diagram illustrating radar detection of a low-flying missile superimposed upon a coverage diagram illustrating his own radar’s vulnerability as defined by the missile’s ESM receiver, only a single execution of the APM CSCI would be required, thereby saving valuable computer resources.

3.10.2 Programming Language and Source Implementation

3.10.2.1 Programming Language

The ANSI Fortran 90 program language standard must be used in the development of the APM CSCI (Ref. 10). This standard consists of the specifications of the language Fortran. With certain limitations the syntax and semantics of the old International Standard commonly known as “FORTRAN 77” are contained entirely within this new International Standard. Therefore, any standard-conforming FORTRAN 77 program is standard conforming under the Fortran 90 Standard. Note that the name of this language, Fortran, differs from that in FORTRAN 77 in that only the first letter is capitalized. The Overview section of the International Standard describes the major additions to FORTRAN 77 in this International Standard. Section 1.3 of the International Standard specifies the bounds of the Fortran language by identifying both those items included and those items excluded. Section 1.4.1 describes the FORTRAN 77 compatibility of the International Standard with emphasis on four FORTRAN 77 features having different interpolations in the new International Standard. The International Standard provides facilities that encourage the design and the use of modular and reusable software.

Section 8.2 of the International Standard describes nine obsolescent features of FORTRAN 77 that are redundant and for which better methods are available in FORTRAN 77 itself. These nine obsolescent features should not be used. These obsolescent features are:

1. **Arithmetic IF** - use the **IF** statement.

2. Real and double precision **DO** control variables and **DO** loop control expressions – use integer.

3. Shared **DO** termination and termination on a statement other than **END DO** or **CONTINUE** – use an **END DO** or a **CONTINUE** statement for each **DO** statement.

4. Branching to an **END IF** statement from outside its IF block – branch to the statement following the **END IF**.

5. Alternate return.
6. PAUSE statement.

7. ASSIGN and assigned GO TO statements.

8. Assigned FORMAT specifiers.

9. cH (nH) edit descriptor.

Remedies for the last five obsolescent features are described in section 8.2 of the International standard.

3.10.2.2 Source Implementation

Ref. 14 by the Naval Oceanographic Office establishes a uniform standard for all software submitted by all contributors to them. It is recommended that the coding requirements set forth in Section 4 of that document be followed. Among these recommendations are:

1. Special non-ANSI features shall be avoided. Non-ANSI practices that are necessary must be documented in the code itself.

2. Maximum use should be made of existing commercially available FORTRAN callable libraries.

3. Programs shall be designed and coded using only five basic control structures – sequence of operations (assignment, add, ...), IF THEN ELSE, DO WHILE, DO UNTIL, and CASE.

4. Procedures or routines that make up a module shall not exceed an average of 100 executable statements per procedure or routine and shall not exceed a maximum of 200 executable statements in any procedure or routine.

5. Branching statements (GO TOs) shall only pass control to a statement that is in the same procedure or routine. Each GO TO must pass control only forward of its point of occurrence.

6. Naming conventions shall be uniform throughout the software. Program, subprogram, module, procedure, and data names shall be uniquely chosen to identify the applicable function performed. The naming convention for COMMON shall be consistent across the entire program.

7. Constants shall be defined not calculated (e.g., do not use \textit{HALF} = \frac{1}{2}, use \textit{HALF} = 0.5)
8. Mixed-mode numerical operations should be avoided whenever possible. When determined to be necessary, the use shall be explicit (FLOAT, FIX, or in assignment statement) and completely described in comments.

9. Each component of the software shall have a prologue containing the name of the program, subprogram, or function and any version number; purpose; inputs; outputs; list of routines that call this routine; complete list of routines called including intrinsic functions such as ABS and FLOAT; glossary; and method.

10. To facilitate program comprehension, comment statements shall be used throughout the program code.

11. The use of the EQUIVALENCE statement shall be restricted to those where it either improves the readability of the code or the efficiency of the program. If the EQUIVALENCE statement is used, it must be fully documented in the prologue and inline comment statements.

12. No machine-dependent techniques are allowed, unless there is no other way of performing the task.

13. Initialize every variable before use.

14. Do not depend on the values of “local” variables computed on a previous call to a routine.

15. Program structural indentation shall be used to improve readability and clarity.

3.11 PERSONNEL-RELATED REQUIREMENTS

Not applicable.

3.12 TRAINING-RELATED REQUIREMENTS

The employing target software personnel implementing this CSCI into the NITES CSCI will require training to become familiar with APM. This requirement should be met by this document and the companion Software Design Description (SDD) and Software Test Description (STD) documents.

3.13 OTHER REQUIREMENTS

None.
3.14 PRECEDENCE AND CRITICALITY OF REQUIREMENTS

The requirements presented in Sections 3.1 through 3.5 and Sections 3.8 through 3.10 have precedence over Sections 3.6, 3.7, 3.11, 3.12, and 3.13 and should be given equal weight.

4. QUALIFICATION PROVISIONS

N/A

5. REQUIREMENTS TRACEABILITY

5.1 SYSTEM TRACEABILITY

This section provides traceability of requirements between the APM CSCI and the NITES CSCI.

1. The APM CSCI environmental data requirements should be obtained from the Tactical Environmental Data System database (TEDS) within the NITES CSCI. The APM CSCI terrain data element requirements should be obtained from the Digital Terrain Elevation Database (DTED) within the NITES CSCI. The radar/communication system data element requirements should be obtained from the EM system database within the NITES CSCI.

2. The NITES CSCI requirement of propagation loss vs. range and height should be obtained from the APM CSCI.

5.2 DOCUMENTATION TRACEABILITY

This section provides the following types of traceability between the Software Requirements Specification (SRS), the Software Design Description (SDD), and the Software Test Description (STD):

1. Traceability between levels of requirements;

2. Traceability between the software requirements and software design;

3. Traceability between the software requirements and qualification test information obtained from the software testing.
This traceability of the Advanced Propagation Model is presented in two tables. The first table, Table 7 given here, presents the traceability between levels of SRS requirements. The second table (Table 6 in the Software Design Document) presents the traceability between the software requirements and software design.
Table 7. Requirements traceability matrix for the SRS.

APPENDIX A

A.1 DEFINITIONS OF QUALITY FACTOR CRITERIA

The criteria for judging the quality factors of Section 3.9 have the following definitions:

1. Accuracy. The precision of computations and control;

2. Anomaly management. The degree to which the program detects failure in order to maintain consistency;

3. Application independence. The degree to which the program is independent of nonstandard programming language features, operating system characteristics, and other environmental constraints;

4. Auditability. The ease with which conformance to standards can be checked;

5. Completeness. The degree to which full implementation of required function has been achieved;

6. Consistency. The use of uniform design and documentation techniques throughout the software development project;

7. Document accessibility. The availability of documents describing the program components;

8. Functional scope. The generality of the feature set and capabilities of the program;

9. Generality. The breadth of potential application of program components;

10. Hardware independence. The degree to which the software is decoupled from the hardware on which it operates;

11. Modularity. The functional independence of program components;

12. Self-descriptiveness. The degree to which the source code provides meaningful documentation;

13. Simplicity. The degree to which a program can be understood without difficulty;
14. System clarity. The ease for which the feature set and capabilities of the system can be determined;

15. Traceability. The ability to trace a design representation or actual program component back to requirements.

A.2 SOFTWARE QUALITY METRICS

A.2.1 Completeness Criteria

The criteria completeness can be determined from the metric:

1. no ambiguous references (input, function, output);

2. all data references defined;

3. all referenced functions defined;

4. all defined functions used;

5. all conditions and processing defined for each decision point;

6. all defined and referenced calling sequences parameters agree;

7. all problem reports resolved;

8. design agrees with requirements;

9. code agrees with design;

10. (score 0 for any untrue statement; 1 otherwise); and

11. metric value = SUM (scores)/9.

A.2.2 Consistency Criteria

The criteria consistency can be determined from the metric: number of modules violating the design standard divided by the number of modules.

A.2.3 Traceability Criteria

The criteria traceability can be determined from the metric: number of itemized requirements traced divided by the total number of requirements.
SOFTWARE DESIGN DESCRIPTION
FOR THE
ADVANCED PROPAGATION MODEL CSCI
(Version 1.3.1)

9 August 2002

Prepared for:
Space and Naval Warfare Systems Command (PMW-155)
San Diego, CA

Prepared by:
Space and Naval Warfare Systems Center, San Diego
Atmospheric Propagation Branch (Code 2858)

1. SCOPE

1.1 IDENTIFICATION

The Advanced Propagation Model (APM) Version 1.3.1 computer software configuration item (CSCI) calculates range-dependent electromagnetic (EM) system propagation loss within a heterogeneous atmospheric medium over variable terrain, where the radio-frequency index of refraction is allowed to vary both vertically and horizontally, also accounting for terrain effects along the path of propagation.

1.2 SYSTEM OVERVIEW

The APM CSCI model is designed to calculate propagation loss values as EM energy propagates through a laterally heterogeneous atmospheric medium where the index of refraction is allowed to vary both vertically and horizontally, also accounting for terrain effects along the path of propagation. Numerous Naval Integrated Tactical Environmental Subsystem (NITES) applications require EM-system propagation loss values. The APM model described by this document may be applied to two NITES applications, one which displays propagation loss on a range versus height scale (commonly referred to as a coverage diagram) and one which displays propagation loss on a propagation loss versus range/height scale (commonly referred to as a loss diagram).

1.3 DOCUMENT OVERVIEW

This document describes the design of the APM CSCI. An overview of the input software requirements is presented together with an overview of the CSCI design architecture and a detailed design description of each component of the CSCI.

2. REFERENCED DOCUMENTS

3. CSCI-WIDE DESIGN DECISIONS

The required APM CSCI propagation model is a range-dependent true hybrid model that uses the complementary strengths of both Ray Optics (RO) and Parabolic Equation (PE) techniques to calculate propagation loss both in range and altitude.

The atmospheric volume is divided into regions which lend themselves to the application of the various propagation loss calculation methods. Figure 1 illustrates these regions.
For antenna elevation angles above 5 degrees or for ranges less than approximately 2.5 kilometers (km), a flat-earth (FE) ray-optics model is used. In this region, only receiver height is corrected for average refraction and earth curvature.

Within the RO region (as defined by a limiting ray), propagation loss is calculated from the mutual interference between the direct-path and surface-reflected ray components using the refractivity profile at zero range. Full account is given to focusing or de-focusing along both direct and reflected ray paths and to the integrated optical path length difference between the two ray paths, to give precise phase difference, and, hence, accurate coherent sums for the computation of propagation loss.

For the low-altitude region beyond the RO region, a PE approximation to the Helmholtz full wave equation is employed. The PE model allows for range-dependent refractivity profiles and variable terrain along the propagation path and uses a split step Fourier method for the solution of the PE. The PE model is run in the minimum region required to contain all terrain and trapping layer heights.

For the area beyond the RO region but above the PE region, an extended optics region (XO) is defined. Within the XO region, ray-optics methods which are initialized by the PE solution described below are used.
APM will run in three “execution” modes depending on environmental inputs. APM will use the FE, RO, XO, and PE models if the terrain profile is flat for the first 2.5 km and if the antenna height is less than or equal to 100 m. It will use only the XO and PE models if the terrain profile is not flat for the first 2.5 km and if the antenna height is less than or equal to 100 m. For applications in which the antenna height is greater than 100 meters, a combination of FE and PE methods are used. The FE model is used for all propagation angles greater than ±5º from the source and the PE model is used for angles less than ±5º. By default, APM will automatically choose which mode of operation it will use for a specified set of inputs. However, the ability to run only the PE model for any case is allowed by setting a logical flag upon input.

The APM CSCI allows for horizontal and vertical antenna polarization, finite conductivity based on user-specified ground composition and dielectric parameters, and the complete range of EM system parameters and most antenna patterns required by NITES. APM also allows for gaseous absorption effects in all sub-models and computes troposscatter losses within the diffraction region and beyond.

The APM CSCI is divided into four main computer software components (CSC) and 47 additional software units (SUs). The purpose of the first CSC, the APMINIT CSC, is to interface with various SUs for the complete initialization of the APM CSCI. The purpose of the second CSC, the APMSTEP CSC, is to advance the entire APM CSCI algorithm one output range step, referencing various SUs to calculate the propagation loss at the current output range. The purpose of the XOINIT CSC is to initialize the range, height, and angle arrays in preparation for the XOSTEP CSC. The purpose of the fourth CSC, the XOSTEP CSC, is to advance the APM CSCI algorithm one output step from the top of the PE calculation region to the maximum output height specified, referencing various SUs to calculate the propagation output range.

4. CSCI ARCHITECTURE DESIGN

4.1 CSCI COMPONENTS

The APM CSCI is accessed by a subroutine call which provides, as global data elements, the values specified in Table 1 through Table 4. The source code for the APM CSCI is listed in Appendix A. The name and purpose for each CSC and SU are listed below.

The Advance Propagation Initialization (APMINIT) CSC interfaces with various SUs for the complete initialization of the APM CSCI. The APMINIT CSC component SUs include the following:

1. **Allocate Arrays APM (ALLARRAY_APM) SU.** Allocates and initializes all dynamically dimensioned arrays associated with APM terrain, refractivity, troposscatter, and general variable arrays.
2. **Allocate Array PE (ALLARRAY_PE) SU.** Allocates and initializes all dynamically dimensioned arrays associated with PE calculations.

3. **Allocate Array RO (ALLARRAY_RO) SU.** Allocates and initializes all dynamically dimensioned arrays associated with RO calculations.

4. **Allocate Array XO (ALLARRAY_XORUF) SU.** Allocates and initializes all dynamically dimensioned arrays associated with XO and rough surface calculations.

5. **Alpha Impedance Initialization (ALN_INIT) SU.** Initializes variables used in the Discrete Mixed Fourier Transform (DMFT) algorithm for finite conductivity and/or rough surface calculations.

6. **Antenna Pattern (ANTPAT) SU.** Calculates a normalized antenna gain (antenna pattern factor) for a specified antenna elevation angle.

7. **Dielectric Initialization (DIEINIT) SU.** Determines the conductivity and relative permittivity as a function of frequency in MHz based on general ground composition types.

8. **FFT Parameters (FFTPAR) SU.** Determines the required transform size based on the maximum PE propagation angle and the maximum height needed.

9. **Fill Height Arrays (FILLHT) SU.** Calculates the effective earth radius for an initial launch angle of 5° and fills an array with height values at each output range of the limiting sub-model, depending on which mode is being used.

10. **Gaseous Absorption (GASABS) SU.** Computes the specific attenuation based on air temperature and absolute humidity.

11. **Get Effective Earth Radius Factor (GET_K) SU.** Computes the effective earth radius factor and the effective earth radius.

12. **Get Alpha Impedance (GETALN) SU.** Computes the impedance term in the Leontovich boundary condition and the complex index of refraction for finite conductivity and vertical polarization calculations.

13. **Get Grazing Angle (GETGRAZE) SU.** Computes the grazing angles at each PE range step for subsequent use in rough sea surface calculations.

14. **Get Maximum Angle (GETTHMAX) SU.** Performs an iterative ray trace to determine the minimum angle required (based on the reflected ray) in obtaining a PE solution.
15. **Grazing Angle Interpolation (GRAZE_INT)** SU. Interpolates grazing angles at each PE range step based on angles computed from ray trace (takes precedence) and those computed from spectral estimation.

16. **Interpolate Profile (INTPROF)** SU. Performs a linear interpolation vertically with height on the refractivity profile.

17. **PE Initialization (PEINIT)** SU. Initializes all variables used in the PE model for subsequent calls to the PESTEP SU.

18. **Profile Reference (PROFREF)** SU. Adjusts the current refractivity profile so that it is relative to a reference height.

19. **RD Trace (RDTRACE)** SU. Performs ray trace of many rays launched within an angle of ±1.5°, storing grazing angles from these rays.

20. **Refractivity Initialization (REFINIT)** SU. Checks for valid environmental profile inputs and initializes refractivity arrays.

21. **Remove Duplicate Refractivity Levels (REMDUP)** SU. Removes any duplicate refractivity levels in the currently interpolated profile.

22. **Terrain Initialization (TERINIT)** SU. Examines and initializes terrain arrays for subsequent use in PE calculations.

23. **Trace to Output Range (TRACE_ROUT)** SU. Traces a single ray, whose launch angle is specified by the calling routine, to each output range.

24. **Troposcatter Initialization (TROPOINIT)** SU. Initializes all variables and arrays needed for subsequent troposcatter calculations.

25. **Starter Field Initialization (XYINIT)** SU. Calculates the complex PE solution at range zero.

The Advanced Propagation Model Step (APMSTEP) CSC advances the entire APM CSCI algorithm one output range step, referencing various SUs to calculate the propagation loss at the current output range. The APMSTEP CSC component SUs include the following:

1. **Airborne Hybrid Model (AIRBORNE)** SU. Determines propagation loss based on flat-earth calculations for the direct ray path only for regions above and below the PE maximum propagation angle.
2. **Calculate Propagation Loss (CALCLOS) SU.** Determines propagation loss from the complex PE field at each output height point at the current output range.

3. **DOSHIft SU.** Shifts the field by the number of bins, or PE mesh heights corresponding to the local ground height.

4. **Discrete Sine/Cosine Fast-Fourier Transform (DRST) SU.** Performs a sine or cosine transform, depending on the value of an integer flag provided by the calling SU, on both the real and imaginary components of the PE field which are passed separately.

5. **Flat-Earth Model (FEM) SU.** Computes propagation loss at a specified range based on flat-earth approximations.

6. **Fast-Fourier Transform (FFT) SU.** Separates the real and imaginary components of the complex PE field into two real arrays and then references the DRST SU.

7. **Free-Space Range Step (FRSTP) SU.** Propagates the complex PE solution field in free space by one range step.

8. **FZLIM SU.** Determines both the propagation factor (in dB) and the outgoing propagation angle at the top of the PE calculation region.

9. **Get Propagation Factor (GETPFAC) SU.** Determines the propagation factor at the specified height in dB.

10. **Get Reflection Coefficient (GETREFCOEF) SU.** Calculates the complex surface reflection coefficient, along with the magnitude and phase angle.

11. **Mixed Fourier Transform (MIXEDFT) SU.** Propagates the PE field in free space one PE range step, applying the Leontovich boundary condition, using the mixed Fourier transform as outlined by Kuttler and Dockery (Ref. 9).

12. **Parabolic Equation Step (PESTEP) SU.** Determines the next output range and begins an iterative loop to advance the PE solution such that for the current PE range, a PE solution is calculated from the solution at the previous PE range. This procedure is to be repeated until the output range is reached.

13. **Ray Trace (RAYTRACE) SU.** Traces a ray from a starting height and range with a specified starting elevation angle to a termination range.

14. **Refractivity Interpolation (REFINTER) SU.** Interpolates both horizontally and vertically on the modified refractivity profiles.
15. **Ray Optics Calculation (ROCALC SU).** Computes the RO components which will be needed in the calculation of propagation loss at a specified range and height within the RO region.

16. **Ray Optics Loss (ROLOSS) SU.** Calculates both the propagation loss and propagation factor values at a specified range and height based upon the components of magnitude for a direct-path and surface-reflected ray and the total phase lag angle between the two rays as determined by the ROCALC SU.

17. **Save Profile (SAVEPRO) SU.** Stores the refractivity profiles at each PE range step from the top of the PE region to the maximum user-specified height.

18. **Spectral Estimation (SPECEST) SU.** Determines, via spectral estimation, the outward propagation angle at the top of the PE calculation region.

19. **Troposcatter (TROPOSCAT) SU.** Determines the loss due to troposcatter and computes the appropriate loss between troposcatter and diffraction in the “transition” region using a method of “bold interpolation.”

The Extended Optics Initialization (XOINIT) CSC initializes the range, height, and angle arrays in preparation for the XOSTEP CSC. The XOINIT CSC component SUs include the following:

1. **Advanced Propagation Model Clean (APMCLEAN) SU.** Deallocates all dynamically dimensioned arrays used in one complete run of APM calculations.

2. **Mean Filter (MEANFILT) SU.** Performs an n-point average smoothing on any array passed to it.

The Extended Optics Step (XOSTEP) CSC advances the APM CSCI algorithm one output range step from the top of the PE calculation region to the maximum output height specified, referencing various SUs to calculate the propagation loss at the current output range. The XOSTEP CSC component SUs include the following:

1. **Extended Optics (EXTO) SU.** Calculates propagation loss and propagation factor, based on extended optics techniques, at the current output range.

**4.2 CONCEPT OF EXECUTION**
The program flow of the APM CSCI is illustrated in Figure 2. Note that the APM CSCI is shown within the context of a calling CSCI application such as one that generates a coverage or loss diagram. The efficient implementation of the APM CSCI will have far reaching consequences upon the design of an application CSCI beyond those mentioned in section 7.1. For example, Figure 2 shows checking for the existence of a previously created APM output file prior to the access of the APM CSCI. The application CSCI will have to consider if the atmospheric or terrain environment has changed since the APM output file was created or if any new height or range requirement is accommodated within the existing APM CSCI output file. Because these and many more considerations are beyond the scope of this document to describe, an application CSCI designer should work closely with the APM CSCI development agency in the implementation of the APM CSCI.

Figure 2. APM CSCI program flow.
4.3 INTERFACE DESIGN

4.3.1 Interface Identification and Diagrams

The APM CSCI interface design consists of one FORTRAN MODULE file for the external and internal data interface, FORTRAN CALL statements for both output data and internal interfacing, and several FORTRAN COMMON blocks for the internal interface. The MODULE file is called APM_MOD. This MODULE’s statements provide several constants, COMMON blocks, and the dynamically allocated array names. The COMMON block names are: 1) APM_VAR, 2) ERRORFLAG, 3) INPUTVAR, 4) REFRACTIVITY, 5) SYSTEMVAR, 6) TERRAIN.

4.3.2 External Interface

The APM CSCI is accessed, through the APMINIT CSC, by a subroutine call from the NITES CSCI which should provide, as global data elements, the values specified in Table 1 through Table 4.

The APM CSCI external data elements, i.e., those data which must be provided by the calling NITES CSCI in the MODULE file prior to the APM CSCI execution can be divided into four classifications. The first is external data related to the atmospheric environment, specified within Table 1; the second is data related to the EM system, specified within Table 2; the third is data related to the implementation of the APM CSCI by the NITES CSCI, specified within Table 3; and the fourth is data related to the terrain information, specified within Table 4. Each table lists the type, units, and bounds of each data element. Table 5 specifies the output data of the APM CSCI model passed back to the calling CSCI via the FORTRAN CALL statements.
Table 1. APM CSCI environmental data element requirements.

aCouplets of height and modified refractivity associated with that height are referred to within this document as a refractivity profile.

bAll heights in the refractivity profile must be steadily increasing.

cThe CCIR gaseous absorption model implemented within APM provides a ±15% accuracy for absolute humidity and surface air temperature within these bounds. While values beyond these limits are allowed within APM, it should be noted this may result in less accurate attenuation rates calculated.

4.3.3 Internal Interface

Section 4.2 shows the relationship between the APM CSCI and its four main CSCIs: APMINIT, AMPSTEP, XOINIT, and XOSTEP. This relationship is illustrated in Figure 2. The internal interface between these three CSCs and the APM CSCI is left to the design. However, the internal structure of the APM CSCI and its CSCs and SUs is shown in Table 6. The left two columns show the calling subroutines, and the right two columns the subroutines called. Columns 2 and 4 in Table 6 give the section number in Section 5 where more details about the various CSCs and SUs of the APM CSCI can be found.
Table 6. APM internal interface design.

### 4.3.4 Internal Data

The APM CSCI takes full advantage of Fortran 90 features, utilizing allocatable arrays for all internal and input arrays. This requires the NITES CSCI designer to correctly allocate and initialize all arrays necessary for input to the APM CSCI.

Due to the computational intensity of the APM CSCI, it may not be necessary or desirable to use the extreme capability of the APM CSCI for all applications. The variables $n_{\text{rout}}$ and $n_{\text{zout}}$ refer to the desired number of range and height output points for any one particular application, and will be specified when the APMINIT CSC is called.

One of the parameters returned to the NITES application from the APMINIT CSC is $i_{\text{error}}$. This allows for greater flexibility in how input data is handled within the NITES application. Table 7 lists all possible errors that can be returned.
The logical variables \textit{lerr6} and \textit{lerr12}, when set to `.false.', allow the NITES application to bypass their associated errors as these are not critical to the operation of the APM CSCI.

The APM CSCI provides propagation loss and factor for all heights and ranges when running in a full hybrid mode. When running in a partial hybrid mode, it provides propagation loss and factor for all heights, but not necessarily for all angles. Finally, it will be limited in both height and angle coverage when running in a PE-only mode. Refer to Section 7.1 for environmental conditions under which each execution mode is automatically selected.

\begin{table}[h]
\centering
\begin{tabular}{|c|p{10cm}|}
\hline
\textit{ierror} & Definition \\
\hline
-6 & Last range in terrain profile is less than \textit{r}_{\text{max}}. Will only return this error if \textit{lerr6} set to `.true.'.
\hline
-7 & Specified cut-back angles (for user-defined height-finder antenna pattern) are not increasing.
\hline
-8 & \textit{h}_{\text{max}} is less than maximum height of terrain profile.
\hline
-9 & Antenna height with respect to mean sea level is greater than maximum height \textit{h}_{\text{max}}.
\hline
-10 & Beamwidth is less than or equal to zero for directional antenna pattern.
\hline
-11 & Number of antenna pattern or power reduction factors and angles is less than or equal to 1. For \textit{ipat} = 6, \textit{n}_{\text{facs}} must be at least 1; for \textit{ipat} = 7, \textit{n}_{\text{facs}} must be at least 2.
\hline
-12 & Range of last environment profile given (for range-dependent case) is less than \textit{r}_{\text{max}}. Will only return this error if \textit{lerr12} set to `.true.'.
\hline
-13 & Height of first level in any user-specified refractivity profile is greater than 0. First height must be at mean sea level (0.0) or < 0.0 if below mean sea level.
\hline
-14 & Last gradient in any environment profile is negative.
\hline
-17 & Range points of terrain profile are not increasing.
\hline
-18 & First range value in terrain profile is not 0.
\hline
-19 & Elevation angle specified is greater than 10° or less than -10°.
\hline
-25 & Specified only the PE model to be used but did not specify maximum propagation angle \textit{\theta}_{\text{max}}.
\hline
-41 & Transmitter height is less than 1.5 meters.
\hline
-42 & Minimum height input by user, \textit{h}_{\text{min}}, is greater than maximum height, \textit{h}_{\text{max}}.
\hline
-43 & Transform size is greater than 2^{30}.
\hline
-44 & Combination of frequency and antenna beamwidth results in antenna physically below the surface. Increase frequency or beamwidth for valid combination.
\hline
-45 & Wind speed specified is greater and 10 m/s.
\hline
\end{tabular}
\caption{APMINIT SU returned error definitions.}
\end{table}
Absorption by atmospheric gases (oxygen and water vapor) may be important to some applications of the APM CSCI and is controlled by specifying a non-zero value for the absolute humidity, \( \text{abs}_{\text{hum}} \), and the surface air temperature, \( t_{\text{air}} \); or likewise, specifying a non-zero value for the gaseous absorption attenuation rate, \( \gamma \).

A particular application of the APM CSCI may or may not require the consideration of troposcatter effects within the propagation loss calculations. For example, a radar evaluation most likely would not be influenced by troposcatter; while an ESM evaluation would. APM has the feature of including or not including the troposcatter calculation by setting a logical flag called \( T_{\text{ropo}} \). Setting this flag to ‘.false.’ would omit the calculation. Setting this flag to ‘.true.’ would include the calculation. For the APM CSCI implementation within the NITES coverage and loss diagram applications, \( T_{\text{ropo}} \) must be set equal to ‘.true.’ so as to include the calculation.

APM by default will run in an “automatic” mode which, depending upon user-specified inputs, will choose the appropriate sub-models to use for a particular application. However, by setting the logical flag \( PE_{\text{flag}} \) to ‘.true.’ this will force APM to use only the PE sub-model for a particular NITES application. By default, this flag is set to ‘.false.’. If this flag is ‘.true.’, then the visible portion of the maximum PE propagation angle, \( th_{\text{max}} \) (i.e., the maximum propagation angle the PE algorithm will accommodate in the field calculations) and the parameter, \( r_{\text{mult}} \), must be specified. By default, \( r_{\text{mult}} \) is equal to 1; however, \( th_{\text{max}} \) does not have a default value and must be explicitly defined. The parameter \( r_{\text{mult}} \) is a range step multiplier, allowing the user to vary the PE range step from the default calculated.

Use this option with caution as you must have some basic knowledge of PE algorithms and how they work to input proper combinations of maximum calculation angles and range steps for a given frequency. *When using this option, most error checking is bypassed and parameter limits can be over-ridden. Erroneous field values may result if a poorly chosen combination of \( th_{\text{max}} \) and \( r_{\text{mult}} \) are used.*

## 5. CSCI DETAILED DESIGN

A description of each component of the APM CSCI is provided in the following subsections.

### 5.1 ADVANCE PROPAGATION MODEL INITIALIZATION (APMINIT) CSC

The purpose of the APMINIT CSC is to interface with various SUs for the complete initialization of the APM CSCI.

Upon entering the APMINIT CSC, several variables are initialized. All internal logical flags controlling certain environmental calculations and errors are initialized.
The wind speeds and ranges are checked to see if they fall within the specified bounds. If not, then an error is returned.

Next, the absorption calculation flag, $k_{abs}$, is set to 1 if the air temperature, $t_{air}$, or the absolute humidity, $abshum$, are non-zero. If an attenuation rate is specified ($\gamma_a \neq 0$), then $k_{abs}$ is set to 2. If the user specifies both $t_{air}$ and $abshum$ to be 0, then $k_{abs}$ is set equal to 0, in which case no absorption losses are computed.

Next, if running the APM CSCI under the hybrid mode ($PE_{flag} = \text{true}$), then the antenna height, the maximum output range, $r_{max}$, the maximum output height, $h_{max}$, and the minimum output height, $h_{min}$, are checked for valid numerical values. If the antenna height is below 1.5 meters, then $i_{error}$ is set to –41 and the APMINIT CSC is exited. $r_{max}$ is set to the value specified from the calling CSCI or 5000 meters, whichever is greater; and $h_{max}$, is set to the value specified from the calling CSCI or 100 meters, whichever is greater. If $h_{min}$ is greater than $h_{max}$, then $i_{error}$ is set to -42 and the APMINIT CSC is exited. If the maximum output range and minimum and maximum output height values are valid, then the APMINIT CSC proceeds to the next step.

The atmospheric volume must be “covered” or resolved with a mesh of calculation points that will, as a matter of routine, exceed the height/range resolution requirements of the particular application of the APM CSCI. The height and range mesh size per APM CSCI output point, $\Delta z_{out}$ and $\Delta r_{out}$, respectively, are calculated from the number of APM output points and the maximum range and height as follows:

$$\Delta r_{out} = \frac{r_{max}}{n_{rout}},$$

$$\Delta z_{out} = \frac{h_{max} - h_{min}}{n_{zout}}.$$

The number of terrain range/height pairs, $i_{pua}$, used for internal calculations is initialized to 1 plus the user-specified number of range/height pairs, $i_{tp}$. The ALLARRAY_APM SU is then referenced to dynamically allocate and initialize all arrays associated with terrain, refractivity, troposscatter, and general variable arrays. If an error has occurred while allocating memory, $i_{error}$ is returned with a non-zero value and the CSC is exited; otherwise, the CSC proceeds to the next step.

Next, the constants used to determine the antenna pattern factor are computed. First, if a user-defined height-finder antenna pattern has been specified ($i_{pat} = 6$), along with power cut-back angles and factors, then the angles are converted to radians and stored in array $hfangr$. If the cut-back angles are not steadily increasing, $i_{error}$ is set to -7 and the CSC is exited; otherwise, the CSC proceeds with the next step.
If a directional antenna pattern has been specified, the antenna vertical beamwidth in degrees, $\mu_{bw}$, is checked for extremely small beamwidth values. If the value is less than or equal to $10^{-4}$, $i_{error}$ is set to -10 and the CSC is exited. If the elevation angle is greater than 10° or less than -10°, then $i_{error}$ is set to -19 and the CSC is exited; otherwise, the CSC proceeds with the next step.

The antenna beamwidth and elevation angles are converted to radians ($\mu_{bwr}$ and $\mu_{or}$, respectively) and the following variables, $ant_{fac}$ and $\mu_{max}$, for use in the ANTPAT SU are determined as follows. If the antenna pattern is Gaussian ($ipat=2$), then $ant_{fac}$ is given by

$$ant_{fac} = \frac{.34657359}{[\sin\left(\frac{\mu_{bwr}}{2}\right)]^2}.$$  

If the antenna pattern is Sin(X)/X ($ipat = 3$), or a generic height finder ($ipat = 5$), then $ant_{fac}$ is given by

$$ant_{fac} = \frac{1.39157}{\sin\left(\frac{\mu_{bwr}}{2}\right)},$$  

and $\mu_{max}$ is given by

$$\mu_{max} = \tan^{-1}\left(\frac{\pi}{ant_{fac}}\sqrt{1 - \left(\frac{\pi}{ant_{fac}}\right)^2}\right).$$  

If running the APM CSCI in hybrid mode, the antenna height is next checked for a valid height based on the combination of frequency and beamwidth specified. The antenna height must not be less than the radius of the antenna and is bounded by

$$ant_{ht} \geq \text{maximum of} \left(1.5, \frac{c_o}{f_{mhz} \mu_{bw}}\right),$$  

where $c_o$ is the speed of light ($299.79 \times 10^6$ m/s).
Next, the TERINIT SU is referenced to initialize all terrain profile and associated arrays. If an error has occurred while in the TERINIT SU, $i_{\text{error}}$ is returned with a non-zero value and the CSC is exited; otherwise, the CSC proceeds with the next step.

If vertical polarization and/or rough surface calculations are required (i.e., a non-zero wind speed is specified), then the flag, $i_{\text{alg}}$, indicating which DMFT algorithm to use, is set to 1 (central difference) for frequencies less than 400 MHz, and is set to 2 (backward difference) for frequencies greater than 400 MHz. The default value for $i_{\text{alg}}$ is 0, in which case, no DMFT algorithm is used for the particular APM application.

Arrays containing all output ranges, $rngout$, 20 times the logarithm of all output ranges, $rlogo$, and the square of the output ranges, $rsqrd$, are initialized accordingly:

\[
\begin{align*}
rngout_i &= i \Delta r_{\text{out}} , \\
rlogo_i &= 20 \log_{10} (i \Delta r_{\text{out}}) , \\
rsqrd_i &= (i \Delta r_{\text{out}})^2 .
\end{align*}
\]

The minimum power of 2 transform, $ln_{\text{min}}$, is next initialized to 10. If the PE-only option is not activated ($PE_{\text{flag}} = \text{'.false.'}$), then the execution mode in which the APM CSC will operate is determined. Based on inputs, it determines whether to use the airborne hybrid mode ($i_{\text{hybrid}}=0$), full hybrid mode ($i_{\text{hybrid}}=1$), or partial hybrid mode ($i_{\text{hybrid}}=2$). For antenna heights greater than 100 meters above the local ground height, $i_{\text{hybrid}}$ is set equal to 0. For antenna heights less than 100 meters, $i_{\text{hybrid}}$ is initialized to 1. If performing a terrain case ($f_{\text{ter}}=\text{'.true.'}$) and the first 2500 meters of the terrain profile is not flat, then $i_{\text{hybrid}}$ is set equal to 2. If running in full hybrid mode ($i_{\text{hybrid}}=1$), then the ALLARRAY_RO SU is referenced to allocate and initialize all arrays associated with RO calculations.

The variable $y_{\text{ref}}$ is initialized to 0. If a terrain profile has been specified ($f_{\text{ter}}=\text{'.true.'}$), then $y_{\text{ref}}$ is set equal to $t_y^1$. Next, the output height arrays $z_{\text{out}}$ and $z_{\text{ro}}$ are initialized as follows:

\[
\begin{align*}
z_{\text{out}}_i &= h_{\text{m}_{\text{ref}}} + i \Delta z_{\text{out}} , \\
z_{\text{ro}}_i &= z_{\text{out}}_i - y_{\text{ref}} ,
\end{align*}
\]

Next, the REFINIT SU is referenced to initialize all refractivity associated arrays. If an error has occurred while in the REFINIT SU, $i_{\text{error}}$ is returned with a non-zero value and the CSC is exited; otherwise, the CSC proceeds to the next step.

If the PE-only option is activated ($PE_{\text{flag}} = \text{'.true.'}$), then the minimum height for the PE calculation region $z_{\text{test}}$ is set equal to $ht_{\text{lim}}$. If the PE-only option is not activated ($PE_{\text{flag}} = \text{'.false.'}$), then output height arrays used in FE calculations are computed:
The limiting grazing angle, $\psi_{\text{lim}}$, is computed as

$$
\psi_{\text{lim}} = \text{MAX}\left(0.02, \frac{0.04443}{f_{\text{MHz}}} \right),
$$

If more than one refractivity profile has been specified ($n_{\text{proj}} > 1$), then $\psi_{\text{lim}}$ is multiplied by 2. It is then adjusted for trapping effects by

$$
\psi_{\text{lim}} = \psi_{\text{lim}} + \sqrt{2(rm_{\text{max}} - rm_{\text{min}})},
$$

where $rm_{\text{max}}$ and $rm_{\text{min}}$ are determined in the REFINIT SU. The RO elevation angle limit, $\alpha_{\text{lim}}$, is given by

$$
\alpha_{\text{lim}} = \sqrt{\psi_{\text{lim}}^2 + 2(rm_{\text{tx}} - refdum)},
$$

where the variable $rm_{\text{tx}}$ and array $refdum$ are determined in the REFINIT SU. Next, the height tolerance, $z_{\text{tol}}$, is initialized to .05, and the range and index variables for the RO region, $i_{\text{ROP}}$ and $x_{\text{RON}}$, are initialized to -1 and 0, respectively. The minimum height for the PE calculation region is determined next. The minimum height encompassing all trapping refractive layers is given by

$$
h_{\text{test}} = h_{\text{trap}} + h_{\text{thick}},
$$

where $h_{\text{trap}}$ and $h_{\text{thick}}$ are determined in the REFINIT SU. If running in full hybrid mode ($i_{\text{hybrid}}=1$), the minimum height for the PE calculation region is given by

$$
z_{\text{test}} = \text{MAX}(h_{\text{test}}, 1.2 h_{\text{term}}),
$$

where $h_{\text{term}}$ is determined in the TERINIT SU. If running in either the partial hybrid mode or PE-only mode, $z_{\text{test}}$ is then given by

$$
z_{\text{test}} = \text{AMAX}(h_{\text{lim}}, ant_{\text{ref}}),
$$
The tangent angle, $a_{\text{test}}$, used for automatic calculation of the maximum propagation angle is given by

$$a_{\text{test}} = \tan^{-1}\left( \frac{z_{\text{test}} + a_{\text{ref}} + \frac{r_{\text{max}}^2}{2a_{\text{ekst}}}}{r_{\text{max}}} \right),$$

with $a_{\text{lim}}$ now set equal to the greater of $a_{\text{test}}$ or the previously determined $a_{\text{lim}}$ and $a_{\text{ekst}}$ is $\frac{\text{z}}{2}$ times the mean earth’s radius. The GET_K SU is then referenced to determine the effective earth’s radius factor.

If rough surface calculations are required ($ruf = \text{'true'}$), then the wavelength, $\lambda$, and the free-space wave number, $k_o$, are initialized using a fixed frequency of 10 GHz ($f_{\text{rfg}}$):

$$\lambda = \frac{c_o}{f_{\text{rfg}}}, \quad k_o = \frac{2\pi}{\lambda}.$$

The maximum PE calculation angle is set equal to the greater of $4^\circ$ ($\text{thmxg}$) or the maximum terrain tangent angle, $\alpha_g$, determined in TERINIT SU. The FFTPAR SU is then referenced to determine PE grid variables and the transform size required. Next, the PEINIT SU is referenced to initialize all arrays and variables associated with the PE calculation algorithm. Variables needed for spectral estimation of the grazing angles are then initialized. The number of bins, $n_p$, considered in the near-surface PE region, is set equal to 16. The power of 2 transform, $\ln p$, is set equal to 9. The following variables used in the spectral estimation calculations are given by

$$n_4 = 2^{\ln p},$$
$$n_{p4} = \frac{n_p}{4},$$
$$n_{p34} = 3n_{p4},$$
$$cn_{p75} = \frac{\pi}{n_{p4}}.$$

The ALLARRAY_XORUF SU is then referenced to allocate and initialize all arrays associated with rough surface calculations. The filter array $\text{filt}_p$ is now determined by

$$\text{filt}_p(i) = \frac{\pi}{4} + \frac{\pi}{4} \cos(i \cdot cn_{p75}), \quad i = 0, 1, 2, ..., n_{p4}.$$
and the variable \( x_{o\text{con}} \) is given by

\[
x_{o\text{con}} = \frac{\lambda}{2 n_s \Delta z_{\text{PE}}}.
\]

The GETGRAZE SU is next referenced to determine all grazing angles for subsequent rough surface calculations. This involves computing a complete PE run out to the maximum range \( r_{\text{max}} \). In doing this, the refractivity arrays initially set in the REFINIT SU must be re-initialized for the second, or “real,” PE run that includes rough surface effects.

If rough surface calculations are not required (\( ruf = \text{‘false.’} \)), then the grazing angle array \( \Psi \) is initialized to 0, with the number of grazing angles, \( i_{\text{grz}} \), set to 1.

Next, the wavelength and free-space wave number are recomputed for the specified frequency \( f_{\text{MHz}} \):

\[
\lambda = \frac{c_o}{f_{\text{MHz}}}, \quad k_o = \frac{2\pi}{\lambda}.
\]

The DIEINIT SU is then referenced to initialize all dielectric ground constants. If rough surface calculations are required, two terms used in the computation of the rough surface reflection coefficient are determined as follows:

\[
ruf_{\text{fac}} = \frac{4\pi \times 0.0051}{\lambda}, \quad ruf_{\text{ht}} = ruf_{\text{fac}} \times \text{wind}_1^2
\]

where \( \text{wind}_1 \) is the first wind speed in m/s provided by the calling CSCI.

If the PE-only option is activated (\( PE_{\text{flag}} = \text{‘true.’} \)), then the maximum propagation calculation angle used in the PE region, \( \Theta_{\text{max}} \), is determined according to:

\[
\Theta_{\text{max}} = \frac{\pi}{5} \times th_{\text{max}}.
\]

The minimum transform size is then set to \( ln_{\text{min}} \) plus 1 for every 5° in \( \Theta_{\text{max}} \). The FFTPAR SU is then referenced to determine the PE grid variables, and the maximum valid height within the PE calculation region, \( z_{\text{lim}} \), is set equal to the smaller of \( z_{\text{test}} \) and \( ht_{\text{lim}} \). The PEINIT SU is then referenced to initialize all PE variables and arrays and, if required (i.e., \( i_{\text{alg}} > 0 \)), the ALN_INIT SU is referenced to initialize all arrays and variables used in the surface impedance calculations.
If the PE-only option is not activated (\(PE_{\text{flag}} = \text{false}'\)) and if using the airborne hybrid mode (\(i_{\text{hybrid}}=0\)), then the maximum PE calculation angle is determined from \(\Theta_{75}\), obtained from the GET_K SU, according to

\[ \Theta_{\text{max}} = \frac{\pi}{3} \Theta_{75}, \]

and the minimum transform size is set to \(ln_{\text{min}} + 1\) for every \(5^\circ\) in \(\Theta_{\text{max}}\). The FFTPAR SU is then referenced to determine the PE grid variables, and the maximum valid height within the PE calculation region, \(z_{\text{lim}}\), is set equal to \(z_{\text{test}}\). If the airborne mode is not the mode of execution (\(i_{\text{hybrid}}\neq 0\)), then the GETTHMAX SU is referenced to determine the minimum angle \(\Theta_{75}\) to use within the PE calculation region. \(z_{\text{lim}}\) is then set equal to the smaller of \(z_{\text{lim}}\) and \(ht_{\text{lim}}\).

In order to determine if XO calculations are required, the following steps 1 through 6 are performed for \(i_{\text{hybrid}}\) not equal to 0.

1. If \(z_{\text{lim}}\) is less than \(ht_{\text{lim}} - 10^{-5}\), then the SU proceeds with steps 2 through 6. Otherwise, these steps are skipped and the output range and index, \(r_{\text{at}}\) and \(i_{\text{rat}}\), respectively, are calculated as

\[ r_{\text{at}} = 2 r_{\text{max}}, \]
\[ i_{\text{rat}} = n_{\text{rot}} + 1. \]

2. The bin number \(jz_{\text{lim}}\), corresponding to \(z_{\text{lim}}\), is given by

\[ jz_{\text{lim}} = \text{INT}\left( \frac{z_{\text{lim}}}{\Delta z_{\text{PE}}} \right), \]

and \(z_{\text{lim}}\) is recomputed such that it corresponds to an integer multiple of bins or mesh heights: \(z_{\text{lim}} = jz_{\text{lim}} \Delta z_{\text{PE}}\).

3. Next, \(r_{\text{at}}\) and \(i_{\text{rat}}\) are determined based on the height, angle, and range arrays \(ht_{\text{temp}}, r_{\text{aya}},\) and \(r_{\text{temp}}\), previously determined in the GETTHMAX SU. First, the index \(j\) is initialized to \(iap\) (previously determined in the GETTMAX SU) and the index \(id\) is initialized to 1. The following steps 3.a through 3.b are repeated until \(j\) is greater than \(i_{\text{temp}}\).

   a. If \(ht_{\text{temp}}\) is greater than \(z_{\text{lim}}\), then the iteration is ended and the SU proceeds with step 4.
b. If $h_{temp}$ is greater than $z_{rtid}$, then $id$ is incremented by 1. The index $j$ is now incremented by 1. Steps 3a through 3b are then repeated.

4. The index $ira$ is set equal to the greater of 1 or $j-1$; the index $idg$ is set equal to $id-1$; and the gradient $g_{rd}$ is set equal to $gr_{idg}$.

5. Next, the ray with initial launch angle $a_{launch}$ is traced from height $h_{temp_{ira}}$ to $z_{lim}$. The square of the local ray angle, $rad$, at the end of the ray trace step is given by

$$rad = raya_{ra}^2 + 2 g_{rd} (z_{lim} - h_{temp_{ira}}).$$

The local ray angle, $a_{atz}$, at height $z_{lim}$ is initialized to 0. If $rad$ is greater than 0, then $a_{atz}$ is given by

$$a_{atz} = \text{SIGN}(1, raya_{ra}) \sqrt{rad},$$

and the range $r_{atz}$ is now given by

$$r_{atz} = r_{temp_{ira}} + \frac{a_{atz} - raya_{ra}}{g_{rd}}.$$

6. If $r_{atz}$ is less than $r_{max}$ and $z_{lim}$ is less than $h_{tlm}$, then the index $k$ is determined such that $rngout_{k} > r_{atz}$ and $rngout_{k-1} < r_{atz}$. Then $i_{atz}$ is set equal to the smaller of $n_{out}$ and $k$, and $i_{xostp}$ is set equal to $i_{ratz}$. The number of XO calculations needed, $i_{xo}$, is then set equal to $i_{xostp}$.

The PEINIT SU is next referenced to initialize all variables and arrays necessary for PE calculations. All variables and arrays associated with XO calculations are now initialized, provided $i_{xo}$ is greater than 0. The maximum number of points, $iz_{max}$, allocated for arrays used in XO calculations, is determined by

$$iz_{max} = \frac{\text{NINT} \left( \frac{r_{max} - r_{atz}}{\Delta r_{PE}} \right)}{iz_{inc}} + 4.$$

Next, variables needed for spectral estimation calculations are initialized. The number of bins, $n_{p}$, considered in the upper PE region, is set equal to 8 if no terrain profile or wind speeds are specified, and 16, otherwise. The power of 2 transform, $ln_{p}$, is set equal to 8. The following variables are given by
\[
\begin{align*}
    n_s &= 2^{n_p}, \\
    n_{p4} &= \frac{n_p}{4}, \\
    n_{p34} &= 3n_{p4}, \\
    cn_{p75} &= \frac{\pi}{n_{p4}}.
\end{align*}
\]

The ALLARRAY_XORUF SU is then referenced to allocate and initialize all arrays associated with XO calculations. The filter array \textit{filtp} is now determined by

\[
    \text{filtp}_i = \frac{1}{2} + \frac{1}{2} \cos \left( i \cdot cn_{p75} \right), \quad i = 0, 1, 2, \ldots, n_{p4},
\]

and the variable \textit{xocon} is given by

\[
    \text{xocon} = \frac{\lambda}{2n_s \Delta z_{pe}}
\]

The ALN_INIT SU is next referenced to initialize all arrays and variables used in the surface impedance calculations, and the FILLHT SU is referenced to obtain the \textit{htfe} array separating the FE from the RO region.

Several variables associated with the beginning, middle, and end of a PE range step, are initialized. If rough surface calculations are required, the GRAZE_INT SU is referenced to interpolate the pre-computed grazing angles (as determined in the GETGRAZE SU) at every output range step. If troposcatter calculations are required \((T_{ropo} = 1)\), then the TROPOINIT SU is referenced to initialize all variables and arrays. An additive loss term \textit{plcnst} and the free-space loss \textit{fsl} are determined at each output range step by

\[
\begin{align*}
    \text{plcnst}_i &= 20 \log_{10} (2k_o), \\
    \text{fsl}_i &= r\log_{10} i + \text{plcnst}_i ; \quad i = 1, 2, \ldots, n_{\text{rout}}.
\end{align*}
\]

Finally, if the absorption flag \(k_{abs} \) is equal to 1, then the GASABS SU is referenced to determine the absorption attenuation rate, \textit{gasatt}. If \(k_{abs} \) is equal to 2, then \textit{gasatt} is determined by the calling CSCI-specified attenuation rate, \(\gamma_a\), multiplied by \(10^{-3}\) to convert \(\gamma_a\) from dB/km to dB/m. Several dynamically allocated terrain arrays used in the TERINIT SU are deallocated and the CSC is exited.
Table 8 and Table 9 identify, describe the purpose for, state the units of, and show the computational source for each input and output data element, respectively, of the APMINIT CSC.

### 5.1.1 Allocate Arrays APM (ALLARRAY_APM) SU

The purpose of the ALLARRAY_APM SU is to allocate and initialize all dynamically dimensioned arrays associated with APM terrain, refractivity, troposcatter, and general variable arrays.

The ALLARRAY_APM SU utilizes the FORTRAN ALLOCATE and DEALLOCATE statements to dynamically size arrays that have been previously declared with the ALLOCATABLE attribute in the APM_MOD MODULE or to free the array storage space previously reserved in an ALLOCATE statement. Each dimension of the ALLOCATABLE array is indicated by a colon in the APM_MOD module (e.g., \(array(:)\)). The ALLOCATE statement establishes the upper and lower bounds of each dimension and reserves sufficient memory. Because attempting to allocate a previously allocated array causes a run-time error, each ALLOCATE statement for an array is preceded by a test to determine if it has been allocated. If it has, it is deallocated first before it is allocated.

Initially, the integer used to indicate an error, \(i_{\text{error}}\), is set to zero. If, in attempting to allocate an array, a value of \(i_{\text{error}}\) other than zero is returned by an ALLOCATE statement, the SU is exited. Note that each array that is dynamically allocated in this SU is initialized to zero.

There are six integers input to this SU that are used to dynamically allocate the arrays. Unless otherwise indicated, these integers are used as the single dimension of the dynamically allocated array. The first, \(i_{gr}\), is the number of different ground types
specified. The second, $i_{pfa}$, is the number of terrain points used internally in arrays $tx$ and $ty$. The third, $lvlp$, is the number of levels in the refractivity profile. The fourth, $nfacs$, is the number of user-defined cut-back antenna pattern factors for the user-defined height-finder antenna type. The fifth, $n_{rout}$, is the integer number of output range points desired. And finally, the sixth, $n_{zout}$, is the integer number of output height points desired.

The definitions of the following arrays allocated in this SU are given in Table 11. The only array that is allocated using the integer $nfacs$ is $hfangr$. The arrays that are allocated using the integer $n_{rout}$ are $rsqrd$, $fsl$, $rlogo$, $hlim$, $htfe$, and $rngout$. The arrays that are allocated using the integer $n_{zout}$ are $zout$, $zoutma$, $zoutpa$, $rfac1$, $rfac2$, and $rloss$. Only those arrays associated with the hybrid mode of execution will be allocated; i.e., if the PE-only mode is activated ($PEflag = \text{.'false'}$), then arrays $rsqrd$, $zoutma$, $zoutpa$, $hlim$, and $htfe$ will not be allocated.

The arrays associated with terrain information use either the integer $i_{pfa}$ or the integer $igr$. The arrays that are allocated with the integer $i_{pfa}$ are $tx$, $ty$, and $slp$. The arrays allocated using the integer $igr$ are $igrnd$, $rgrnd$, and $nc2$. The array $dielec$ is allocated using two as the first dimension and $igr$ as the second dimension. While arrays $igrnd$, $rgrnd$, and $dielec$ are usually specified by the calling CSCI, it is not necessary when performing an over-water case. In this case, $igr$ can have a value of 0, and these arrays will be defaulted to size of one element with a sea-surface ground type.

All refractivity arrays used in the PE algorithm are allocated using the integer $lvlp$ and include $refdum$, $hidum$, $grdum$, $href$, and $reffr$. The arrays associated with troposcatter calculations use either integers $n_{zout}$ and $n_{rout}$ and will be allocated only if troposcatter calculations are required for the particular APM CSCI application ($Tropo = \text{.'true.'}$). The arrays allocated using the integer $n_{zout}$ include $adif$, $d2s$, $rdt$, and $\theta2s$, and the array allocated for size $n_{rout}$ is $\varnothing$.

Table 10 and Table 11 identify, describe the purpose for, state the units of, and show the computational source for each input and output data element, respectively, of the ALLARRAY_APM SU.

### 5.1.2 Allocate Array PE (ALLARRAY_PE) SU

The purpose of the ALLARRAY_PE SU is to allocate and initialize all dynamically dimensioned arrays associated with PE calculations.

The ALLARRAY_PE SU utilizes the FORTRAN ALLOCATE and DEALLOCATE statements to dynamically size arrays that have been previously declared with the ALLOCATABLE attribute in the APM_MOD module or to free the array
storage space previously reserved in an ALLOCATE statement. Each dimension of the ALLOCATABLE array is indicated by a colon in the APM_MOD MODULE (e.g., array(:)). The ALLOCATE statement establishes the upper and lower bounds of each dimension and reserves sufficient memory. Because attempting to allocate a previously allocated array causes a run-time error, each ALLOCATE statement for an array is preceded by a test to determine if it has been allocated. If it has, it is deallocated first before it is allocated.

Initially, the integer used to indicate an error, ierror, is set to zero. If in attempting to allocate an array, a value of ierror other than zero is returned by an ALLOCATE statement, then the SU is exited. Note that each array that is dynamically allocated in this SU is initialized to zero.

There are two integers input to this SU that are used to dynamically allocate the arrays. Unless otherwise indicated, these integers are used as the single dimension of the dynamically allocated array. The first, nfft, is the transform size. The second, n4, is the transform size nfft divided by four.

The definitions of the following arrays allocated in this SU are given in Table 13. The arrays that are allocated using the integer nfft are envpr, frsp, U, Ulast, ht, profint, udum, rn, w, and ym. The only array allocated using the integer n4 is filt. If rough sea surface or finite conductivity calculations are not required (ruf = ‘.false.’ and lpol = 0), then arrays rn, w, and ym will not be allocated.

Table 12 and Table 13 identify, describe the purpose for, state the units of, and show the computational source for each input and output data element, respectively, of the ALLARRAY_PE SU.

5.1.3 Allocate Array RO (ALLARRAY_RO) SU

The purpose of the ALLARRAY_RO SU is to allocate and initialize all dynamically dimensioned arrays associated with RO calculations.

The ALLARRAY_RO SU utilizes the FORTRAN ALLOCATE and DEALLOCATE statements to dynamically size arrays that have been previously declared with the ALLOCATABLE attribute in the APM_MOD MODULE or to free the array storage space previously reserved in an ALLOCATE statement. Each dimension of the ALLOCATABLE array is indicated by a colon in the APM_MOD module (e.g., array(:,)). The ALLOCATE statement establishes the upper and lower bounds of each dimension and reserves sufficient memory. Because attempting to allocate a previously allocated array causes a run-time error, each ALLOCATE statement for an array is preceded by a test to determine if it has been allocated. If it has, it is deallocated first before it is allocated.

Initially, the integer used to indicate an error, $i_{error}$, is set to zero. If in attempting to allocate an array, a value of $i_{error}$ other than zero is returned by an ALLOCATE statement, then the SU is exited. Note that each array that is dynamically allocated in this SU is initialized to zero.

There are two integers input to this SU that are used to dynamically allocate the arrays. Unless otherwise indicated, these integers are used as the single dimension of the dynamically allocated array. The first of these is $lvlp$, the number of points in the
refractivity profile, and the second is \( n_{z\text{out}} \), which is the number of output height points desired.

The definitions of the following arrays allocated in this SU are given in Table 15. The array \( z\text{ro} \) is allocated using the integer \( n_{z\text{out}} \). The remainder of the arrays associated with refractivity information, \( gr, q, rm, \) and \( z\text{rt} \), are allocated using the integer \( lvlpt \), which is equal to \( lvlp \) plus one.

Table 14 and Table 15 identify, describe the purpose for, state the units of, and show the computational source for each input and output data element, respectively, of the ALLARRAY_RO SU.

### 5.1.4 Allocate Array XORUF (ALLARRAY_XORUF) SU

The purpose of the ALLARRAY_XORUF SU is to allocate and initialize all dynamically dimensioned arrays associated with XO and rough sea surface calculations.

The ALLARRAY_XORUF SU utilizes the FORTRAN ALLOCATE and DEALLOCATE statements to dynamically size arrays that have been previously declared with the ALLOCATABLE attribute in the APM_MOD MODULE or to free the array storage space previously reserved in an ALLOCATE statement. Each dimension of the ALLOCATABLE array is indicated by a colon in the APM_MOD module (e.g., \( array(:, :) \)). The ALLOCATE statement establishes the upper and lower bounds of each dimension and reserves sufficient memory. Because attempting to allocate a previously allocated array causes a run-time error, each ALLOCATE statement for an array is preceded by a test to determine if it has been allocated. If it has, it is deallocated first before it is allocated.
Initially, the integer used to indicate an error, $i_{error}$, is set to zero. If in attempting to allocate an array, a value of $i_{error}$ other than zero is returned by an ALLOCATE statement, then the SU is exited. Note that each array that is dynamically allocated in this SU is initialized to zero.

There are six integers input to this SU that are used to dynamically allocate the arrays. Unless otherwise indicated, these integers are used as the single dimension of the dynamically allocated array. The first of these is $ixo$ and is the number of XO range step calculations required. The second is $iz_{max}$, the maximum number of points allocated for arrays associated with XO calculations. The third is $lvlp$, the number of points in the refractivity profile. The fourth is $np4$, $1/4$ of the number of points, $np$, used in the top or bottom portion of the PE region for spectral estimation. The fifth is $nrout$, the number of output range points desired, and the last is $ns$, the transform size used in spectral estimation calculations (i.e., $ns=2^{lnp}$), where the integer $lnp$ is the power of 2 transform size.

The definitions of the following arrays allocated in this SU are given in Table 17. The array $ffrout$ is allocated using the integer $nrout$ as the first dimension and two as the second dimension. The integer $iz_{max}$ is used as the first dimension limit, and the integer three is used as the second dimension in the allocation of the array $ffacz$. Both of the arrays, $grad$ and $htr$ are allocated with the first dimension given by $lvlp$ and the second dimension given by $iz_{max}$. The array $lvl$ is allocated using the integer $iz_{max}$. The array $filtp$ is allocated using the integer $np4$. The three arrays $xp$, $yp$, and $spectr$ are allocated using the integer $ns$.

If no XO calculations are required ($ixo = 0$), then the arrays $ffrout$, $ffacz$, $grad$, $htr$, and $lvl$ will not be allocated.

Table 16 and Table 17 identify, describe the purpose for, state the units of, and show the computational source for each input and output data element, respectively, of the ALLARRAY_XORUF SU.

5.1.5 Alpha Impedance Initialization (ALN_INIT) SU

The purpose of the ALN_INIT SU is to initialize variables and arrays used for either the backward or central difference form of the DMFT algorithm. The DMFT algorithm is used only for finite conductivity and/or rough sea surface calculations.

Upon entering, the GETALN SU is referenced to obtain the surface impedance, \( \alpha_s \), the complex root \( R_T \), the array \( rn \) containing the powers of the complex root, and a coefficient \( R_k \) used in the central difference algorithm. These variables are computed from the grazing angle \( \psi \) and current range, which, for initialization purposes are set equal to \( \frac{\pi}{2} \) and 0, respectively.

If the central difference algorithm is required (\( i_{alg}=1 \)) for the particular APM CSCI application, then coefficients necessary for this form of the DMFT are computed as follows:

\[
ck_1 = R_k \left[ 0.5 \left( U_0 + U_{n_{m}} r_{n_{m}} \right) + \sum_{i=1}^{n_{nl}} U_i r_n \right]
\]

\[
ck_2 = R_k \left[ 0.5 \left( U_0 r_{n_{m}} + U_{n_{m}} \right) + \sum_{i=1}^{n_{nl}} (-1)^i U_{n_{m}-i} r_n \right]
\]
If the backward difference algorithm is required \((i_{alg}=2)\) for the particular APM CSCI application, then the variable \(cmft\) is initialized using the starting PE field \(U\) and the array \(rn\) according to

\[
cmft = \sum_{i=1}^{n_{m1}} U_i r_{n_i}.
\]

Table 18 and Table 19 identify, describe the purpose for, state the units of, and show the computational source for each input and output data element, respectively, of the ALN_INIT SU.

**5.1.6 Antenna Pattern (ANTPAT) SU**

The purpose of the ANTPAT SU is to calculate an antenna pattern factor (normalized antenna gain), \(f(\alpha)\), for a specified antenna elevation angle, \(\alpha\). Currently, antenna pattern factors are included for six types of antennas. These patterns include an omni-directional \((i_{pat}=1)\) type; a Gaussian \((i_{pat}=2)\) type; a Sin(X)/X \((i_{pat}=3)\) type; a cosecant-squared \((i_{pat}=4)\) type; a generic height-finder \((i_{pat}=5)\) type; a user-defined height-finder type \((i_{pat}=6)\), in which the calling CSCI must also specify an array of cut-back
angles and pattern factors; and finally, a user-defined antenna type \( (i_{\text{pat}} = 7) \), in which the calling CSCI must specify an array of antenna pattern factors and angles.

From two antenna pattern parameters, \( \text{antfac} \) and \( p_{\text{ele}} \); the antenna beam width, \( \mu_{\text{bwr}} \); and elevation angle, \( \mu_{\text{or}} \); a specified angle, \( \alpha \), for which the antenna pattern factor is desired; and the antenna radiation pattern type, \( i_{\text{pat}} \), the antenna factor is calculated as follows.

If the antenna pattern is omni-directional, then \( f(\alpha) = 1 \). If the antenna pattern is Gaussian, then

\[
f(\alpha) = e^{-\text{antfac} \left[ \sin(\alpha) - p_{\text{ele}} \right]^2}.
\]

If the antenna pattern is cosecant-squared, compute the elevation angle relative to the antenna elevation angle as

\[
\alpha_{\text{pat}} = \alpha - \mu_{\text{or}}.
\]

The antenna pattern is now given as

\[
f(\alpha) = \frac{s_{\text{bwr}}}{\sin(\alpha_{\text{pat}})}, \quad \text{for } \alpha_{\text{pat}} > \mu_{\text{bwr}},
\]

\[
f(\alpha) = \text{MAX} \left( 0.03, \left[ 1 + \frac{\alpha_{\text{pat}}}{\mu_{\text{bwr}}} \right] \right), \quad \text{for } \alpha_{\text{pat}} < 0,
\]

\[
f(\alpha) = 1 \quad \text{otherwise},
\]

where \( s_{\text{bwr}} \) is determined in the APMINIT CSC.

If the antenna pattern is \( \sin(X)/X \), a generic height-finder, or a user-specified height-finder, the following calculations are made.

1. The elevation angle relative to the antenna elevation angle, \( \alpha_{\text{pat}} \), is determined as in the previous definition. If the antenna radiation pattern type is a generic or user-specified height-finder, the radiation pattern is simulated as a \( \sin(X)/X \) type with the elevation angle adjusted to account for the current pointing angle of the main beam, \( \chi \). \( \chi \) is set equal to the antenna elevation angle \( \mu_{\text{or}} \). If the direct-path ray angle, \( \alpha_{\text{dp}} \), is
greater than the antenna elevation angle, then $\alpha_{pat}$ is computed as $\alpha_{pat} = \alpha - \alpha_d$ and $\chi$ is set equal to $\alpha_d$.

2. The antenna pattern is now given as

$$f(\alpha) = \begin{cases} 1 & \text{for } |\alpha_{pat}| \leq 10^{-6} \\ \frac{\sin[\text{antfac} \sin(\alpha_{pat})]}{\text{antfac} \sin(\alpha_{pat})} & \text{for } |\alpha_{pat}| < \mu_{max}, \\
\end{cases}$$

$$f(\alpha) = .03, \text{ otherwise.}$$

For a user-defined height-finder, the pattern factor is further adjusted by a power reduction factor, $hffaci$, as

$$f(\alpha) = f(\alpha) hffaci; \quad i = n_{facs}, \ldots, 2, 1$$

where $i$ is an angle counter, decremented by one from the number of power reduction angles, $n_{facs}$, for each power reduction angle, $hfangri$, which exceeds $\chi$.

For the user-defined antenna type, the antenna pattern factor is simply the array $hffac$ provided by the calling CSCI at angles $hfangr$, where pattern factors are interpolated from $hffac$ for angles $\alpha$ within $hfangr$.

Table 20 and Table 21 identify, describe the purpose for, state the units of, and show the computational source for each input and output data element, respectively, of the ANTPAT SU.

5.1.7 Dielectric Initialization (DIEINIT) SU

The purpose of the DIEINIT SU is to determine the conductivity and relative permittivity as a function of frequency in MHz based on general ground composition types.
The DIEINIT SU supports the following general ground types: salt water, fresh water, wet ground, medium dry ground, very dry ground, ice at -1°C, ice at -10°C, and user-defined. For all ground types other than “user-defined,” the permittivity and conductivity are calculated as functions of frequency from curve fits to the permittivity and conductivity graphs shown in the Recommendations and Reports of the International Radio Consultative Committee (Ref. 4). For the $i^{th}$ input ground type case, $igrnd_i$, the permittivity $\varepsilon_r$ and conductivity $\sigma$ are determined as follows:

For salt water ($igrnd_i = 0$), the relative permittivity is given by $70$ for $f_{MHz} \leq 2253.5895$; and the conductivity is given by $5.0$ S/m for $f_{MHz} \leq 1106.207$. For $f_{MHz} > 2253.5895$, the relative permittivity is given by

$$\varepsilon_r = \left[ 1.4114535 \times 10^{-2} - 5.2122497 \times 10^{-8} f_{MHz} + 5.8547829 \times 10^{-11} f_{MHz}^2 \right]^{-1} - 7.6717423 \times 10^{-16} f_{MHz}^3 + 2.9856318 \times 10^{-21} f_{MHz}^4$$

For $f_{MHz} > 1106.207$, the conductivity $\sigma$ in S/m is given by

$$\sigma = \frac{3.8586749 + 9.1253873 \times 10^{-4} f_{MHz} + 1.530992 \times 10^{-8} f_{MHz}^2}{1 - 2.1179295 \times 10^{-5} f_{MHz} + 6.5727504 \times 10^{-10} f_{MHz}^2 - 1.9647664 \times 10^{-15} f_{MHz}^3}$$

For fresh water ($igrnd_i = 1$), the relative permittivity $\varepsilon_r$ is given by $80$ for $f_{MHz} \leq 6165.776$. For higher frequencies, $\varepsilon_r$ is given by

$$\varepsilon_r = \frac{7.9027635 - 3.5486650 \times 10^{-4} f_{MHz} + 8.210184 \times 10^{-9} f_{MHz}^2}{1 - 2.2083308 \times 10^{-5} f_{MHz} + 2.7067836 \times 10^{-10} f_{MHz}^2 - 1.0007669 \times 10^{-14} f_{MHz}^3}$$

For $f_{MHz} > 5776.157$, the conductivity $\sigma$ in S/m is given by

$$\sigma = \left( \frac{-6.5750351 + 6.6113198 \times 10^{-4} f_{MHz} + 1.4876952 \times 10^{-9} f_{MHz}^2}{1 + 5.5620223 \times 10^{-5} f_{MHz} + 3.0140816 \times 10^{-10} f_{MHz}^2} \right)^2$$

For $f_{MHz} \leq 5776.157$, the conductivity $\sigma$ in S/m is given by

$$\sigma = \left( \frac{2.0197103 + 1.2197967 \times 10^{-2} f_{MHz} - 1.728776 \times 10^{-6} f_{MHz}^2}{1 - 2.5539582 \times 10^{-3} f_{MHz}^2 - 3.7853169 \times 10^{5} f_{MHz}^2} \right)^{-1}$$
For wet ground \((igrnd_i = 2)\), the relative permittivity \(\varepsilon_r\) is given by 30 for \(f_{MHz} \leq 1312.054\). For \(1312.054 < f_{MHz} < 4228.11\), the relative permittivity \(\varepsilon_r\) is given by

\[
\varepsilon_r = \sqrt{\frac{857.94335 + 5.5275278 \times 10^{-2} f_{MHz}}{1.89983662 \times 10^{-5} f_{MHz} + 8.8247139 \times 10^{-8} f_{MHz}^2}}.
\]

For \(f_{MHz} \geq 4228.11\), the relative permittivity \(\varepsilon_r\) is given by

\[
\varepsilon_r = \sqrt{\frac{915.31026 - 4.0348211 \times 10^{-3} f_{MHz} + 7.4342897 \times 10^{-7} f_{MHz}^2}{1.94530022 \times 10^{-6} f_{MHz} + 4.892281 \times 10^{-8} f_{MHz}^2}}.
\]

For \(f_{MHz} > 15454.4\), the conductivity \(\sigma\) in S/m for wet ground is given by

\[
\sigma = 0.8756665 + 4.7236085 \times 10^{-5} f_{MHz} + 2.6051966 \times 10^{-8} f_{MHz}^2
- 9.235936 \times 10^{-13} f_{MHz}^3 + 1.4560078 \times 10^{-17} f_{MHz}^4
- 1.1129348 \times 10^{-22} f_{MHz}^5 + 3.3253339 \times 10^{-28} f_{MHz}^6.
\]

For \(f_{MHz} \leq 15454.4\), the conductivity \(\sigma\) in S/m for wet ground is given by

\[
\sigma = 5.5990969 \times 10^{-3} + 8.7798277 \times 10^{-5} f_{MHz} + 6.2451017 \times 10^{-8} f_{MHz}^2
- 7.1317207 \times 10^{-12} f_{MHz}^3 + 4.2515914 \times 10^{-16} f_{MHz}^4
- 1.240806 \times 10^{-20} f_{MHz}^5 + 1.3854354 \times 10^{-25} f_{MHz}^6.
\]

For medium dry ground \((igrnd_i = 3)\), the relative permittivity \(\varepsilon_r\) is given by 15 for \(f_{MHz} \leq 4841.945\). For \(f_{MHz} > 4841.945\), the relative permittivity \(\varepsilon_r\) is given by

\[
\varepsilon_r = \sqrt{\frac{215.87521 - 2.6151055 \times 10^{-3} f_{MHz} + 1.9484482 \times 10^{-7} f_{MHz}^2}{1.76649237 \times 10^{-5} f_{MHz} + 1.2565999 \times 10^{-8} f_{MHz}^2}}.
\]

At \(f_{MHz} \leq 4946.751\) for medium dry ground, the conductivity \(\sigma\) in S/m is given by

\[
\sigma = (2.4625032 \times 10^{-2} + 1.8254018 \times 10^{-4} f_{MHz} - 2.664754 \times 10^{-8} f_{MHz}^2
+ 7.6508732 \times 10^{-12} f_{MHz}^3 - 7.4193268 \times 10^{-16} f_{MHz}^4)^2.
\]

For \(f_{MHz} > 4946.751\), for medium dry ground, the conductivity \(\sigma\) in S/m is given by
\[ \sigma = (0.17381269 + 1.2655183 \times 10^{-4} f_{\text{MHz}} - 1.6790756 \times 10^{-9} f_{\text{MHz}}^2 + 1.1037608 \times 10^{-14} f_{\text{MHz}}^3 - 2.9223433 \times 10^{-20} f_{\text{MHz}}^4)^2. \]

For very dry ground \((i\text{grnd}_d = 4)\), the relative permittivity \(\varepsilon_r\) is given by 3 and the conductivity \(\sigma\) in S/m is 0.0001 for \(f_{\text{MHz}} < 590.8924\). For \(590.8924 \leq f_{\text{MHz}} \leq 7131.933\), the conductivity \(\sigma\) in S/m is given by

\[
\sigma = 2.2953743 \times 10^{-4} - 8.1212741 \times 10^{-7} f_{\text{MHz}} + 1.8045461 \times 10^{-9} f_{\text{MHz}}^2 - 1.960677 \times 10^{-12} f_{\text{MHz}}^3 + 1.256959 \times 10^{-15} f_{\text{MHz}}^4 - 4.46811 \times 10^{-19} f_{\text{MHz}}^5 + 9.4623158 \times 10^{-23} f_{\text{MHz}}^6 - 1.1787443 \times 10^{-26} f_{\text{MHz}}^7 + 7.9254217 \times 10^{-31} f_{\text{MHz}}^8 - 2.2088286 \times 10^{-35} f_{\text{MHz}}^9. 
\]

For \(f_{\text{MHz}} > 7131.933\ MHz\), the conductivity \(\sigma\) in S/m is given by

\[
\sigma = (-4.9560275 \times 10^{-2} + 2.9876572 \times 10^{-5} f_{\text{MHz}} - 3.0561848 \times 10^{-10} f_{\text{MHz}}^2 + 1.1131828 \times 10^{-15} f_{\text{MHz}}^3)^2. 
\]

For ice at -1°C \((i\text{grnd}_d = 5)\), the relative permittivity \(\varepsilon_r\) is 3 for all frequencies, and the conductivity \(\sigma\), for \(f_{\text{MHz}} \leq 300\), is given by

\[
\sigma = \frac{3.8814567 \times 10^{-5} + 9.878241 \times 10^{-6} f_{\text{MHz}} + 7.9902484 \times 10^{-8} f_{\text{MHz}}^2}{1 + 8.467523 \times 10^{-2} f_{\text{MHz}} - 9.736703 \times 10^{-5} f_{\text{MHz}}^2 + 3.269059 \times 10^{-7} f_{\text{MHz}}^3}, 
\]

and for \(f_{\text{MHz}} > 300\) is given by

\[
\sigma = \frac{1.2434792 \times 10^{-4} + 8.680839 \times 10^{-7} f_{\text{MHz}} + 7.2701689 \times 10^{-11} f_{\text{MHz}}^2 - 2.6416983 \times 10^{-14} f_{\text{MHz}}^3 + 1.37552 \times 10^{-18} f_{\text{MHz}}^4}{1 + 8.24598 \times 10^{-4} f_{\text{MHz}} - 6.755389 \times 10^{-4} f_{\text{MHz}}^2 + 2.8728975 \times 10^{-12} f_{\text{MHz}}^3 - 6.795958 \times 10^{-18} f_{\text{MHz}}^4}. 
\]

For ice at -10°C \((i\text{grnd}_d = 6)\), the relative permittivity \(\varepsilon_r\) is 3 for all frequencies, and the conductivity \(\sigma\), for \(f_{\text{MHz}} \leq 8753.398\), is given by

\[
\sigma = \frac{1 + 3.883854 \times 10^{-2} f_{\text{MHz}} + 6.832108 \times 10^{-5} f_{\text{MHz}}^2}{51852.543 + 389.58894 f_{\text{MHz}}}, 
\]

and for \(f_{\text{MHz}} > 8753.398\), is given by

\[
\sigma = 4.13105 \times 10^{-5} + 2.03589 \times 10^{-7} f_{\text{MHz}} - 3.1739 \times 10^{-12} f_{\text{MHz}}^2 + 4.52331 \times 10^{-17} f_{\text{MHz}}^3. 
\]
For the user-defined ground type \((igrndi = 7)\), the relative permittivity \(\varepsilon_r\) and the conductivity \(\sigma\) in S/m are set equal to the input values \(\text{dielec}_{1,i}\) and \(\text{dielec}_{2,i}\), respectively.

Finally, the complex dielectric constant is given by

\[
nc_i^2 = \varepsilon_r + 60\lambda \sigma; \quad \text{for } i = 1, 2, 3, \ldots, I_{gr}.
\]

Table 22 and Table 23 identify, describe the purpose for, state the units of, and show the computational source for each input and output data element, respectively, of the DIEINIT SU.

### 5.1.8 FFT Parameters (FFTPAR) SU

The purpose of the FFTPAR SU is to determine the required transform size based on the maximum PE propagation angle and the maximum height needed for desired
coverage. If running in full or partial hybrid modes, the maximum height is the height necessary to encompass at least 20% above the maximum terrain peak along the path or the highest trapping layer specified in the environment profiles, whichever is greater. If running in a PE-only mode, the maximum height is the specified maximum output height.

For computational efficiency reasons, an artificial upper boundary is established for the PE solution. To prevent upward propagating energy from being “reflected” downward from this boundary and contaminating the PE solution, the PE solution field strength is attenuated or “filtered” above a certain height to ensure that the field strength just above this boundary is reduced to zero. The bin width in z-space $\Delta z_{PE}$ is found from

$$\Delta z_{PE} = \frac{\lambda}{2 \sin(\Theta_{max})}$$

where $\lambda$ is the wavelength in meters and $\Theta_{max}$ is the maximum propagation angle in radians.

The flag, $i_{flag}$, is used to determine maximum FFT size based on a given $\Theta_{max}$ and desired coverage height $z_{lim}$ or it will determine $z_{lim}$ based on a given $\Theta_{max}$ and FFT size.

For $i_{flag}=0$, the constants $ln_{fft}$, $n_{fft}$, and $z_{max}$ are found from $ln_{min}$ as follows,

$$ln_{fft} = ln_{min},$$
$$n_{fft} = 2^{ln_{fft}},$$
$$z_{max} = n_{fft} \Delta z_{PE},$$

where $ln_{min}$ is the minimum power of two transform size. $ln_{min}$ is initialized to 10 and for every $5^\circ$ in $\Theta_{max}$ is increased by 1. Next, the transform size needed to perform calculations to a test height $z_t$ is determined. First, $z_t$ is set equal to $z_{lim}$ minus a small height precision tolerance. Then a DO WHILE loop is executed as long as the condition $3/4 z_{max} < z_t$ is satisfied. Within this DO WHILE loop $z_{max}$ is found from

$$ln_{fft} = ln_{fft} + 1,$$
$$n_{fft} = 2^{ln_{fft}},$$
$$z_{max} = n_{fft} \Delta z_{PE},$$

If $ln_{fft}$ reaches the value of 30, then the SU is exited with a non-zero error code.

For the case where $i_{flag}=1$, no iteration needs to be performed. $z_{lim}$ is determined by a given $ln_{fft}$ and $\Theta_{max}$ from equations shown above.
Upon exiting, $z_{lim}$ is computed as $\frac{3}{4} z_{max}$.

Table 24 and Table 25 identify, describe the purpose for, state the units of, and show the computational source for each input and output data element, respectively, of the FFTPAR SU.

5.1.9 Fill Height Arrays (FILLHT) SU

The purpose of the FILLHT SU is to calculate the effective earth radius for an initial launch angle of $5^\circ$ and to fill an array with height values at each output range of the limiting sub-model, depending on which mode is being used. If running in a full hybrid mode, the array contains height values at each output range separating the PE from the RO region. If running in partial hybrid or PE-only modes, the array contains those height values at each output range at which the initial launch angle has been traced to the ground or surface. These height values represent the separating region where, above that height, valid loss is computed, and below that height, no loss is computed. This is done so that only loss values that fall within a valid calculation region are output.

Upon entering the SU, internal one-line ray trace functions are defined as
\[
\text{RADA} 1(a, b) = a^2 + 2g_{rd}b,
\]
\[
\text{RP}(a, b) = a + \frac{b}{g_{rd}},
\]
\[
\text{AP}(a, b) = a + bg_{rd},
\]
\[
\text{HP}(a, b) = a + \frac{b^2 - c^2}{2g_{rd}},
\]

for general parameters \(a, b, c\), and refractivity gradient \(g_{rd}\).

For the case when \(i_{\text{hybrid}} = 1\) (full hybrid mode), all height values at each output range separating the FE region from the RO region, are determined and stored in array \(htfe\). For ranges greater than 2.5 km, the ray defined by a 5° elevation angle is traced up to the maximum height \(ht_{lim}\). The ray is “traced” by simple geometry at every output range and the height array \(htfe\) is determined as follows. The temporary variable \(y_{ar}\) is found from

\[
y_{ar} = y_{ref} - \text{ant}_{ref},
\]

where the parameter \(y_{ref}\) is the ground elevation height at the source, and \(\text{ant}_{ref}\) is the transmitting antenna height relative to the height \(h_{minter}\). The values of \(htfe_i\) are then determined by

\[
htfe_i = y_{ref}; \quad \text{for } \text{rng}_{out_i} \leq r_{lst}
\]
\[
htfe_i = \text{MIN}(ht_{lim}, \text{MAX}\{y_{ref}, y_{ar} + t_5 \text{rng}_{out_i}\}); \quad \text{for } \text{rng}_{out_i} > r_{lst}, i = 1, 2, \ldots n_{\text{rout}}
\]

where \(r_{lst}\) is a constant range of 2,500 meters, \(t_5\) is the tangent of 5°, and \(\text{rng}_{out_i}\) is the output range at every \(i^{th}\) range step.

For the airborne hybrid model \((i_{\text{hybrid}} = 0)\) the TRACE ROUT SU is referenced to determine the heights at every output range separating the upper FE region from the PE region. These heights are stored in array \(h_{lim}\). The heights separating the lower FE region from the PE region are stored in array \(htfe\) as outlined below.

For partial hybrid (PE plus XO) or airborne modes, the initial launch angle is traced until it hits the surface, storing heights traced at each output range.

First, several variables are initialized. The angle at the start of the trace, \(a_{0,}\), is set to \(-a_{\text{launch}}\) (determined in the GETTHMAX SU); the initial range, \(r_0\), is set equal to zero; and the height at the start of the ray trace step, \(h_0\), is set equal to \(\text{ant}_{ref}\). The index, \(l\),
indicating the location of the source height in array $htdum$, is set equal to the index $i_{start1}$. The terrain elevation at the current range, $tyr$, is initialized to 0, and the index $j$ is set equal to one.

The following steps (1 through 3) are performed until the ray has reached the surface or the ray has been traced to $r_{max}$, whichever comes first.

1. The output range to trace to, $ro$, is initialized to $rngoutj$, and $htfej$ is initialized to 0.

2. Now, the following steps 2a through 2d are performed until $r_0$ has reached $ro$, the ray has turned around within a refractive layer, or the ray has hit the surface, whichever comes first.

   a. The range at the end of the ray trace step, $r_1$, is initialized to $ro$. The refractivity gradient, $grd$, is set equal to $grdum1$. The angle and height at the end of the trace step, $a_1$ and $h_1$, are now given by

   $$a_1 = AP(a_0, r_1 - r_0),$$
   $$h_1 = HP(h_0, a_1, a_0).$$

   b. If a terrain profile has been specified ($fter = \text{.true.}$), then the terrain elevation at the current traced range $r_1$ is determined according to

   $$tyh_{r} = tyh_{k} + tyh_{k+1} \left( \frac{r_1 - r_k}{r_{k+1} - r_k} \right)$$

   where $tyh$ is the array of terrain elevations sampled at every PE range step $\Delta r_{PE}$ and $tyh_k$ is the terrain height at the $k^{th}$ range step $r_k$ equal to $k\Delta r_{PE}$.

   c. For negative values of $a_1$, the height $h_1$ is first checked to determine if the ray height $h_1$ has fallen below the current terrain height $tyh_r$. If so, $h_1$ is set equal to $tyh_r$ and a new angle and range are re-computed

   $$a_1 = -\sqrt{RADA1(a_0, h_1 - h_0)},$$
   $$r_1 = RP(r_0, a_1 - a_0).$$

   If the ray has been traced through a lower refractive layer, then the index $l$ is decremented by one and $h_1$ is now set to $htdum_l$. A new angle and range $a_1$ and $r_1$ are re-computed as above.
d. $a_0$, $r_0$, and $h_0$ are now set equal to the values of $a_1$, $r_1$, and $h_1$, respectively. If one of the conditions in step 2 has been met, then the SU proceeds to step 3; otherwise, steps 2a through 2d are repeated.

3. The ray has now been traced to output range $rng_{outj}$ and height $h_0$ at that range is stored in array $htfe$. The index $j$ is incremented by one and if the ray has not reached the surface or $r_{max}$, then steps 1 through 3 are repeated.

Once the ray trace is completed, the index $j$ is decremented by one and $htfe_j$ is set equal to $hm_{ref}$ for all remaining output range steps $j$ through $n_{rout}$.

Table 26 and Table 27 identify, describe the purpose for, state the units of, and show the computational source for each input and output data element, respectively, of the FILLHT SU.

5.1.10 Gaseous Absorption (GASABS) SU

The purpose of the GASABS SU is to compute the specific attenuation based on air temperature and absolute humidity. This SU is based on CCIR (International Telecommunication Union, International Radio Consultative Committee, now the ITU-R) Recommendation 676-1, “Attenuation by Atmospheric Gases in the Frequency Range 1-350 GHz.”

The oxygen absorption for 15°C air temperature is computed from

\[
\gamma_o = 10^{-3}\left(t_1 + t_2 + 0.00719\right)\left(\frac{f_{MHz}}{1000.}\right)^2,
\]

where \(f_{MHz}\) is the frequency in MHz and the temporary variables \(t_1\) and \(t_2\) are given by

\[
t_1 = \frac{6.09}{\left(\frac{f_{MHz}}{1000.}\right)^2 + 0.227},
\]

\[
t_2 = \frac{4.81}{\left(\frac{f_{MHz}}{1000.} - 57.0\right)^2 + 1.50}.
\]
A correction is made for the oxygen absorption for the actual air temperature, which is given by

$$\gamma_o = (1.0 + 0.01\{t_{air} - 15.0\}) \gamma_o$$

where $t_{air}$ is the surface air temperature in degrees C.

The water vapor absorption is computed from

$$\gamma_w = \frac{(0.05 + 0.0021 \text{abs}_{\text{hum}} + t_1 + t_2 + t_3)(\frac{f_{MHz}}{1000.})^2 \text{abs}_{\text{hum}}}{10000.0}$$

where the temporary variables $t_1$, $t_2$, and $t_3$ are given, respectively, by

$$t_1 = \frac{3.6}{\left(\frac{f_{MHz}}{1000.} - 22.2\right)^2 + 8.5}$$

$$t_2 = \frac{10.6}{\left(\frac{f_{MHz}}{1000.} - 1833\right)^2 + 9.0}$$

and

$$t_3 = \frac{8.9}{\left(\frac{f_{MHz}}{1000.} - 3254\right)^2 + 26.3}$$

The total specific absorption for sea-level air in dB/km multiplied by a conversion factor to convert to dB/m is given by

$$\text{gas}_{\text{att}} = (\gamma_o + \gamma_w)10^{-3}.$$

5.1.11 Get Effective Earth Radius Factor (GET_K) SU

The purpose of the GET_K SU is to compute the effective earth radius factor and the effective earth radius. The computation is made for a launch angle of 5° if the SU is called from the APMINIT CSC. If called from the TROPOINIT SU, then the computation is made for a launch angle equal to the critical angle.

Upon entering the SU, internal one-line ray trace functions are defined as

$$ RADA_1(a, b) = a^2 + 2g_{rd}b, $$

$$ RP(a, b) = a + \frac{b}{g_{rd}}, $$

for general parameters $a$, $b$, and refractivity gradient $g_{rd}$.

The starting launch angle $a_{start}$ for tracing a ray to determine the effective earth radius is initialized to the critical angle $a_{crit}$.

If the SU is called from the APMINIT CSC ($i_{org} = 0$), then $a_{start}$ is re-initialized to 5°. If running the airborne model, then the beamwidth and antenna elevation angle are taken into account and the starting angle is initialized according to

$$ a_{start} = \min\left[\max\left(a_{start}, \mu_{incr} + \mu_{lim}\right), 10^\circ\right], $$

where

$$ \mu_{lim} = \min\left(10^\circ, \left|\mu_{cor}\right|\right). $$
If a terrain profile has been specified \( (f_{\text{ter}} = \text{.true.}) \), then \( a_{\text{start}} \) is set equal to

\[
a_{\text{start}} = \text{MIN}(1.5 a_{\text{start}}, 10').
\]

If using the airborne or full hybrid modes, or if calling from the TROPOINIT SU, then the following steps 1 through 4 are performed to compute the effective earth radius from the antenna height up to height \( h_{\text{lim}} \).

1. The propagation angle, range, and height at the start of the ray trace step are initialized to \( a_{\text{start}}, 0., \) and \( \text{ant}_\text{ref} \), respectively. The current refractivity level \( i \) is also initialized to \( i_{\text{start}} \).

2. The following steps 2a through 2c are performed for an upward ray until it has reached the last height in the refractivity level or \( h_{\text{lim}} \), whichever comes first.
   a. The gradient \( g_{\text{rd}} \) is set equal to \( g_{\text{dum}} \). The propagation angle \( a_{1} \) and range \( r_{1} \) at the end of the trace step are computed as

\[
a_{1} = \sqrt{\text{RADA} 1(a_{0}, h_{\text{dum}_{i+1}}-h_{0})},

r_{1} = \text{RP}(r_{0}, a_{1}-a_{0}).
\]

b. \( a_{0}, r_{0}, \) and \( h_{0} \) are now set equal to the values of \( a_{1}, r_{1}, \) and \( h_{\text{dum}_{i+1}} \), respectively.
   If \( h_{0} \) is greater than \( h_{\text{lim}} \), then the integer flag \( i_{\text{flag}} \) is set equal to 1, and the propagation angle \( a_{1} \) at \( h_{\text{lim}} \) is computed:

\[
a_{1} = \sqrt{\text{RADA} 1(a_{0}, h_{\text{lim}}-h_{\text{dum}_{i}})}.
\]

A temporary maximum propagation angle \( \Theta_{75a} \) is then set equal to \( a_{1} \).

c. The current refractivity level \( i \) is incremented by 1. If one of the conditions in step 2 has been met, then the SU proceeds to step 3; otherwise, steps 2a through 2c are repeated.

3. If \( h_{0} \) is less than \( h_{\text{lim}} \) and \( i_{\text{flag}} \) is equal to 0, then propagation angle \( a_{1} \) at \( h_{\text{lim}} \) is re-computed as

\[
a_{1} = \sqrt{\text{RADA} 1(a_{0}, h_{\text{lim}}-h_{0})},
\]

and the variable \( \Theta_{75a} \) is then set equal to \( a_{1} \).
4. The propagation angle and range $a_1$ and $r_1$ are now re-computed from

$$a_1 = \sqrt{\text{RADA} \left( a_0, htdum_{\text{step}} - h_0 \right)},$$
$$r_1 = \text{RP} \left( r_0, a_1 - a_0 \right),$$

and the effective earth radius $a_{ek}$, the effective earth radius factor $e_{k}$, and twice the effective earth radius, $twoka$ are given by

$$a_{ek} = \frac{r_1}{a_1 - a_{\text{start}}},$$
$$twoka = 2a_{ek},$$
$$e_{k} = 6.37 \times 10^{-6} a_{ek}.$$

If using the airborne hybrid model and the calling SU is the APMINIT CSC, then twice the effective earth radius factor is computed for a downward ray where the initial launch angle is $-a_{\text{start}}$. Steps 1 through 2a are repeated with $a_1$ negative, $i$ decremented by 1, and $htdum_{i+1}$ replaced with $htdum_i$. Finally, the variable $twoka_{\text{down}}$ is computed from

$$twoka_{\text{down}} = \frac{2r_1}{a_1 + a_{\text{start}}},$$

and $\Theta_{75}$ is determined from

$$\Theta_{75} = \text{MAX}(\Theta_{75a}, a_{\text{start}}).$$

Table 30 and Table 31 identify, describe the purpose for, state the units of, and show the computational source for each input and output data element, respectively, of the GET_K SU.

5.1.12 Get Alpha Impedance (GETALN) SU

The purpose of the GETALN SU is to compute the surface impedance term in the Leontovich boundary condition and the complex index of refraction for finite conductivity. The implementation of these impedance formulas follow Kuttler and Dockery’s method (Ref. 8).

Upon entering the SU, the smooth surface impedance term, $\alpha$, is computed from the complex dielectric constant $n_c^2$ and free-space wave number $k_o$, for both vertical and horizontal polarization, by

$$
\alpha_h = ik_o \sqrt{n_c^2 - 1},
$$

$$
\alpha_v = ik_o \frac{\sqrt{n_c^2 - 1}}{n_c^2}
$$

where $i$ is the imaginary number $\sqrt{-1}$.

If rough surface calculations are required ($ruf = .true.$) and a non-zero grazing angle $\psi$ exists for the current range step, then the rough surface reflection coefficient, $\Gamma$, is determined from referencing the GETREFCOEF SU and the surface impedance is re-computed as

$$
\alpha_{h,v} = ik_o \sin \psi \frac{1 - \Gamma_{h,v}}{1 + \Gamma_{h,v}},
$$

where the subscripts $h,v$ indicate horizontal and vertical polarization quantities, respectively.

If using the central difference algorithm ($i_{alg} = 1$), the following steps 1 through 2 are performed to compute constants and variables for subsequent use in the MIXEDFT SU.

1. The determination of the complex root, $R_T$, of the quadratic equation for the mixed transform method is based on Kuttler’s formulation

$$
R_T = -\sqrt{1.0 + (\alpha_h \Delta z_{PE})^2 - \alpha_h \Delta z_{PE}} \quad \text{for horizontal polarization},
$$

$$
R_T = \sqrt{1.0 + (\alpha_v \Delta z_{PE})^2 - \alpha_v \Delta z_{PE}} \quad \text{for vertical polarization}
$$

2. Next, the array $m$ is determined according to
\[ r_n = R^*_T. \quad i = 1, 2, \ldots, n_{\text{fft}}. \]

Several parameters used in the central difference algorithm are now computed:

\[ R_k = \frac{2(1-r_n)}{(1+r_n)^2}, \]

\[ C_{1x} = e^{i\Delta r_{PE}} \left( k_0^2 - \left( \frac{L_N(R_T)}{\Delta z_{PE}} \right)^2 \right)^{1/2}, \]

\[ C_{2x} = e^{i\Delta r_{PE}} \left( k_0^2 + \left( \frac{L_N(R_T) - i\pi}{\Delta z_{PE}} \right)^2 \right)^{1/2}. \]

If using the backward difference algorithm \((i_{\text{alg}} = 2)\) \(R_T\) is computed as

\[ R_T = \left( 1 + a_{h,v} \Delta z_{PE} \right), \]

the array \(rn\) is computed as in step 2 above and the parameter \(cmft_x\) is computed using the same equation for \(C_{1x}\) in step 2 above.

5.1.13 Get Grazing Angle (GETGRAZE) SU

The purpose of the GETGRAZE SU is to compute grazing angles at each PE range step via ray trace and spectral estimation for subsequent use in rough sea surface calculations. This SU is referenced only if rough surface calculations are required ($ruf = \text{'.true.'}$).

Upon entering the SU, the RDTRACE SU is referenced to determine the grazing angles $\psi_{ray}$ from ray trace.

If a terrain profile has been specified ($f_{ter} = \text{'.true.'}$) and a surface-based duct has been specified ($l_{duct} = \text{'.true.'}$), then the grazing angles $\psi_{PE}$ are computed from spectral estimation of the near-surface PE field by running the PE algorithm out to the maximum range $r_{max}$, assuming horizontal polarization and smooth surface conditions (i.e., no wind speed).
First, the array $\psi_{PE}$ is allocated for size of $i_{PE}$ – equal to the number of PE range steps required to propagate the field out to $r_{max}$. The array is initialized to zero, with the first element initialized to $\pi/2$ radians. The current PE range $r$ and PE integer step $i_{PE_{step}}$ are then set equal to zero, with the terrain height $y_{last}$ at the previous range step set equal to $tyh_0$ if a terrain profile has been specified, or 0 otherwise. An iterative DO WHILE loop is then begun to advance the PE solution such that for the current PE range, a PE solution is calculated from the solution at the previous PE range. This iterative procedure is repeated in the DO WHILE loop until $r$ is greater than $r_{max}$. The following steps (1 through 5) are performed for each PE range step within the DO WHILE loop.

1. The current PE calculation range $r$ is incremented by one PE range step, $\Delta r_{PE}$, and the PE range step counter $i_{PE_{step}}$ is incremented by 1. The range at which interpolation for range-dependent refractivity profiles is performed, $r_{mid}$, is also incremented by one-half the PE range step.

2. If performing a terrain case ($f_{ter} = \text{.true.}$), the ground heights, $y_{cur}$ and $y_{curm}$, at range $r$ and $r_{mid}$, respectively, are determined according to

$$y_{cur} = tyh_{i_{PE_{step}}},$$
$$y_{curm} = \frac{1}{2} (tyh_{i_{PE_{step}}-1} + y_{cur}).$$

If $y_{cur}$ is less than $y_{curm}$, the DOSHIFT SU is referenced to adjust the PE field relative to the terrain height.

The PE field array $U$ is now propagated in free space one range step by referencing the FRSTP SU.

If the APM CSCI is being used in a range-dependent mode (i.e., the number of profiles $n_{prof}$ is greater than 1), or a terrain profile is specified, the REFINTER SU is referenced to compute a new modified refractive index profile, $prof_{int}$, adjusted by the local ground height $y_{curm}$ at range $r_{mid}$. A new environmental phase array, $envpr$, based on this new refractivity profile is then computed from

$$envpr_j = e^{i \Delta r_{PE} prof_{int}}; \quad j = 1,2,\ldots,n_{fft}$$

$$envpr_j = \text{filt}_{j-n_{34}} envpr_j; \quad j = n_{34}, n_{34}+1, n_{34}+2, \ldots, n_{fft}$$

3. The complex field $U$ is now multiplied by the environmental phase array for all bins from 0 through $n_{fft}-1$. 

69
4. Next, if a terrain profile has been specified and the terrain slope is positive \( (y_{cur} > y_{curm}) \), the DOSHIFT SU is referenced to adjust the PE field relative to the terrain height.

5. The SPECEST SU is then referenced to determine the grazing angle \( \vartheta_{out} \), and this angle is stored in array \( \psi_{PE} \). If no terrain has been specified and the range is greater than the horizon range \( r_{hors} \), then the grazing angle stored is the smaller of the tangent angle \( a_{cut} \) or \( \vartheta_{out} \).

Finally, \( i_{gPE} \), the number of grazing angles computed, is initialized to \( i_{PE} \) and the SU is exited.

Table 34 and Table 35 identify, describe the purpose for, state the units of, and show the computational source for each input and output data element, respectively, of the GETGRAZE SU.

5.1.14 Get Maximum Angle (GETTHMAX) SU

The purpose of the GETTHMAX SU is to perform an iterative ray trace to determine the minimum angle required (based on the reflected ray) in obtaining a PE solution. The determination of this angle depends on the particular mode of execution. For full and partial hybrid modes, a ray is traced up to a height that exceeds at least 20% above the maximum terrain peak along the path or the highest trapping layer specified in the environment profiles, whichever is greater. Heights and angles of this ray are stored at each output range. The maximum PE propagation angle, \( \Theta_{max} \), is then determined from the local maximum angle of the traced ray. For the full hybrid mode, the minimum PE propagation angle is required to meet the following criteria: (1) the top of the PE region must contain all trapping layers for all refractivity profiles; (2) the top of the PE region must be at least 20% higher than the highest peak along the terrain profile; and (3) the minimum PE propagation angle must be at least as large as the grazing angle of the limiting ray \( \psi_{lim} \).

First, four in-line ray trace functions are defined for general parameters \( a, b, c \), and \( g_{rd} \):

\[
\text{RADA } 1(a,b) = a^2 + 2g_{rd}b,
\]
The first parameter to be determined is the minimum PE angle limit $a_{\text{mlim}}$. The parameter to be determined later, $\Theta_{\text{max}}$, must be at least this value. The initial estimate of $a_{\text{mlim}}$ is given by

$$a_{\text{mlim}} = \pi/60 \left( -f_{\text{MHz}}^{248.4} + \frac{f_{\text{MHz}}}{2862} + 1.42e^{-2867} + 0.4091e^{-2495} \right).$$

If the DMFT algorithm is required based on the specified inputs, the antenna height is greater than 5 meters, or the frequency is greater than 15 GHz, then $a_{\text{mlim}}$ is decreased by $1/2$.

If the central difference DMFT algorithm will be used, then $a_{\text{mlim}}$ is adjusted to accommodate low antenna heights according to

$$a_{\text{mlim}} = \text{MAX} \left( a_{\text{mlim}}, \sin^{-1} \left( \frac{\lambda}{2 \text{ant ht}} \right) \right).$$

A multiplicative height factor $h_{\text{mt}}$ is determined to ensure clearance of the ray path for low antenna heights over large terrain elevations:

$$h_{\text{mt}} = \text{MIN} \left( 2, \frac{\text{ant ht}}{\text{MAX} (t_y1, 1)} \right).$$

If $h_{\text{mt}}$ is less than .1, then it is set equal to 0. It is then increased by 1.

Several constants needed in subsequent steps in this SU are determined. An initial estimate of the launch angle $a_{\text{launch}}$ is initialized to $\alpha_{\text{lim}}$, the elevation angle of the RO limiting ray. If using the full hybrid mode, then $a_{\text{launch}}$ is set equal to the negative of $a_{\text{launch}}$. The maximum height to trace to, $z_{\text{limt}}$, is set equal to $ht_{\text{limt}} \times 10^{-5}$, and the range step, $\Delta r_{\text{temp}}$, for subsequent ray tracing is given by $r_{\text{max}}/200$. The terrain elevation height at the source, $y_{\text{nts}}$, is initialized to $t_y1$ provided APM is running in a full hybrid mode and $t_y1$ is greater than zero; otherwise, $y_{\text{nt}}$ is initialized to 0.
An iterative ray trace to determine the launch angle $a_{\text{launch}}$ and subsequently $\Theta_{\text{max}}$ is then begun. The following steps steps 1 through 3 are performed until a ray has been safely traced from height $\text{antref}$ to $z_{\text{lim}}$.

1. At the start of the ray trace, the current local angle ($a_0$), range ($r_0$), height ($h_0$), and refractive gradient index ($j$) are initialized to $a_{\text{launch}}$, 0, $\text{antref}$, and $i_{\text{start}}$, respectively. The counter index, $k_t$, for the terrain profile arrays $t_x$ and $t_y$ is initialized to one. The variable $r_o$, the current output range to trace to, is set equal to zero. The following steps 1.a through 1.d are then performed for each ray trace step from 1 to $i_{\text{temp}}$.

   a. First, $r_o$ is incremented by $\Delta r_{\text{temp}}$. Now the following steps i through vii are performed until $r_0$ reaches $r_o$.

      i. The range at the end of the ray trace step, $r_1$ is set equal to $r_o$, and the current refractive gradient $g_{\text{rd}}$ is set equal to $g_{\text{rdum}}j$

      ii. The angle at the end of the trace, $a_1$, is then given by

      $$a_1 = \text{AP}(a_0, r_1 - r_0).$$

      iii. If $a_1$ is of the opposite sign of $a_0$, then $a_1$ is set to zero, and $r_1$ is given by

      $$r_1 = \text{RP}(r_0, a_1 - a_0).$$

      iv. The height at the end of the ray trace $h_1$ is given by

      $$h_1 = \text{HP}(h_0, a_1, a_0).$$

      v. If $a_1$ is positive and $h_1$ has reached or surpassed the next height level, then $a_1$, $r_1$, $j$, and $h_1$, are found as follows. First, $h_1$ is set equal to $h_{\text{dum}}j+1$, and $a_1$ and $r_1$ are given by

      $$a_1 = \sqrt{\text{RADA}1(a_0, h_1 - h_0)},$$

      $$r_1 = \text{RP}(r_0, a_1 - a_0).$$

      The index $j$ is incremented by one, and the height, $h_1$, at the end of the ray trace step is given by the smaller of $h_{\text{lim}}$ or $h_{\text{dum}}j$.

      vi. However, if either of the conditions for $a_1$ and $h_1$ in step v are not met, and $a_1$ is less than or equal to 0, then $h_1$ is set equal to $y_{\text{nt}}$ if the calculated value in
step iv is less than $y_{nt}$. If the calculated value of $h_1$ in step iv is less than $htdum_j$, then $h_1$ is set equal to $htdum_j$, and $j$ is set equal to the maximum of 0 or $j-1$. The variables $a_1$ and $r_1$ are then determined from

$$a_1 = -\sqrt{RADA_1(a_o, h_1 - h_0)}$$
$$r_1 = RP(r_0, a_1 - a_o)$$

vii. If the ray has hit the surface and is reflected, which would be the condition for which $h_1$ is set equal to $y_{nt}$ in step vi, then $a_1$ is set equal to minus $a_1$, $\psi_{lim}$ is set equal to $a_1$, the range, $r_{pest}$ (at which loss values from the PE model will start being calculated) is set equal to $r_1$, and the height $h_{start}$ is set equal to $y_{nt}$. The variable $h_{start}$ is used for subsequent initialization of ray tracing to fill in array $h_{lim}$. In preparation for the next ray trace step, $h_0$ is set equal to $h_1$, $r_0$ is set equal to $r_1$, and $a_0$ is set equal to $a_1$. If the range $r_1$ is greater than $r_{flat}$, then the current iteration is exited and the SU proceeds to step b; otherwise, steps i through vii are repeated until $r_0$ reaches $r_o$.

b. If running a terrain case ($f_{ter} = \text{‘true.’}$), at the end of the ray trace for the current step a check is made to see that the current height of the ray is at least 20% higher than the current terrain height. The counter $kt$ is determined such that $r_0 > tx_{kt+1}$ and $kt > i_{pa}$. If using the partial hybrid mode and range $r_0$ is less than 5 km, then the clearance height of the terrain, $y_n$, at the current range for the traced ray, is given by

$$y_n = h_{nt} [y_{kt} + s l p_{kt} (r_0 - tx_{kt})].$$

If the previous conditions are not met, then $h_{nt}$ in the above equation is replaced with the constant 1.2.

c. The ending angle, range, and height for each ray trace step is now stored in arrays $raya$, $rtemp$, and $htemp$, respectively.

d. Now, if running a full hybrid case ($i_{hybrid} = 1$), a test is made to determine if both $h_0$ is less than $y_n$ and if $r_0$ is greater than $r_{flat}$. If these conditions are true, then the flag $i_{quit}$ is set equal to 1. If the case is not a full hybrid case and if $h_0$ is less than $y_n$, then $i_{quit}$ is set equal to 1. Finally, if $h_0$ is greater than or equal to $z_{lim}$, or $i_{quit}$ equals 1, then the current iteration is exited and the SU proceeds to step 2; otherwise, the steps 1.a through 1.d are repeated.

2. If the iteration defined by steps 1.a through 1.d has been prematurely terminated ($i_{quit}=1$), then the initial elevation angle $a_{launch}$ is decreased by $10^{-3}$ radians for the full hybrid case ($i_{hybrid} = 1$), and is increased by $10^{-3}$, otherwise. If the previous iteration has not been prematurely terminated ($i_{quit}=0$), the SU continues with step 3.
3. If height $z_{\text{lim}}$ is reached, then an initial launch angle (i.e., ray) has been found with all traced heights, ranges, and angles stored. The integer flag to continue ray tracing, $i_{\text{ray}}$, is set to equal 1 to terminate the iterative loop, and the index $i_{\text{hmax}}$, indicating the range step at which $z_{\text{lim}}$ is reached, is set equal to the range step index $i$ (the range step index counter in the iterative loop defined by steps 1 through 3).

The remaining elements from $i_{\text{hmax}}$ to $i_{\text{temp}}$ in arrays $htemp$, $rtemp$, and $raya$ are filled with the values $h_0$, $r_{\text{max}}$, and $a_0$, respectively. Next, the index $i_{\text{hmax}}$ is set equal to the minimum of $i_{\text{hmax}}$ or $i_{\text{temp}}$.

The variable $\Theta_{\text{max}}$ is found for the PE region based on the local ray angles just determined for the particular ray traced. First, the index $i_{\text{ap}}$ at which the local ray angle becomes positive (i.e., $raya_{\text{ap}}$) is determined. If $i_{\text{ap}}$ equals $i_{\text{temp}}$ this indicates that no PE calculations are required for the specific geometry, in which case the flag $\text{noPE}$ is set equal to 1, $\Theta_{75}$ is set equal to $a_{\text{lim}}$, $r_{\text{pest}}$ is set equal to $r_{\text{max}}$, $z_{\text{lim}}$ is set equal to $ht_{\text{lim}}$, and the SU is exited. Otherwise, several variables are next initialized. The local indices, $i_{\text{ok}}$ and $i_{\text{flag}}$, plus the variables $z_{\text{lim}}$ and $a_{\text{mxcur}}$, are each set equal to zero. The variable $a_{\text{mxcur}}$ is the maximum local angle along the traced ray up to height $z_{\text{lim}}$ with a minimum limit of $a_{\text{lim}}$.

The variable $\Theta_{\text{max}}$ is then found from an iteration performed on the local angle and height at which the local maximum angle is reached. The following steps 1 through 6 are performed while the flag $i_{\text{ok}}$ is 0.

1. The height in the PE region that must be reached for the hybrid model is $z_{\text{test}}$. The first occurrence of $ht_{\text{temp}}$ that is greater than $z_{\text{test}}$ is found and the index $i_{\text{st}}$ is then set to the smaller of the index $j$ where this occurs or $i_{\text{hmax}}$.

2. The angle $a_{\text{mxcur}}$ is now initialized to $raya_1$. The maximum angle in $raya$ is then found looking only at elements from $raya_2$ to $raya_{\text{ist}}$ and $a_{\text{mxcur}}$ is set equal to this angle.

3. $a_{\text{mxcur}}$ is now set equal to the maximum of $a_{\text{lim}}$ and $a_{\text{mxcur}}$. The variable $a_{\text{temp}}$ is now set to $a_{\text{mxcur}}$ divided by 0.75. If using the partial hybrid mode ($i_{\text{hybrid}}=2$), $z_{\text{test}}$ is given by

$$z_{\text{test}} = \text{MAX}(ant_{\text{ref}}, h_{\text{test}}, 1.2 h_{\text{term}}, 10^3).$$

4. A reference is then made to the FFTPAR SU to determine new values for $z_{\text{test}}$, $z_{\text{max}}$, $\Delta z_{\text{PE}}$, $ln_{\text{fii}}$, and $n_{\text{fii}}$ using the inputs: $ln_{\text{min}}$, $\lambda$, $a_{\text{temp}}$, and $i_{\text{flag}}$.

5. After the reference to the FFTPAR SU is made, if $i_{\text{flag}} = 0$ it is set equal to 1. In addition, if not running a full hybrid case, $i_{\text{ok}}$ is set equal to 1. However, if after the
reference to the FFTPAR SU is made, \( i_{\text{flag}} \) is equal to one, and if the case is not a partial hybrid case; the iterative height tolerance \( tol \) is given by

\[
tol = \frac{|z_{\text{test}} - z_{\text{lim}}|}{z_{\text{test}}}.
\]

A test is then made to determine whether this value of \( tol \) is less than or equal to \( z_{\text{tol}} \), the height tolerance for Newton’s method. If it is, then the index \( i_{\text{ok}} \) is set equal to one.

6. Now \( z_{\text{lim}} \) is set equal to \( z_{\text{test}} \), and if \( i_{\text{ok}} \) is 0, steps 1 through 6 are repeated. Otherwise, the SU proceeds to the next step.

The variable \( \Theta_{\text{75}} \) is now set equal to \( \alpha_{\text{max}} \), and \( \Theta_{\text{max}} \) is set equal to \( \alpha_{\text{temp}} \). The variable \( ln_{\text{ffr}} \) is then adjusted such that for every 5° in \( \Theta_{\text{75}} \), it is increased by 1.

Next, the TRACE ROUT SU is referenced to trace the ray to each output range step, \( \Delta r_{\text{out}} \), storing heights in array \( h_{\text{lim}} \). If running in a full hybrid mode, the ray is traced from starting angle, range, and height equal to \( \psi_{\text{lim}} \), \( r_{\text{pest}} \), and \( h_{\text{start}} \), respectively. Otherwise, the starting angle, range, and height are equal to \( \alpha_{\text{launch}} \), 0, and \( \alpha_{\text{ref}} \), respectively.

Before exiting, all elements of \( h_{\text{lim}} \) corresponding to ranges less than \( r_{\text{pest}} \) are set equal to \( y_{\text{ref}} \).

Table 36 and Table 37 identify, describe the purpose for, state the units of, and show the computational source for each input and output data element, respectively, of the GETTHMAX SU.

5.1.15 Grazing Angle Interpolation (GRAZE_INT) SU

The purpose of the GRAZE_INT SU is to interpolate for each PE range step grazing angles computed from both ray trace and spectral estimation. Those angles from ray trace take precedence.

Upon entering the SU, the grazing angle array $\Psi$ is allocated for size $i_{PE}$ and initialized to 0, with the first element initialized to $\frac{1}{2}\pi$ radians. Several variables are next initialized. The variable $r$ which is the range to interpolate to, is initialized to $\Delta r_{PE}$. The
range $r_{grz}$ at which the spectrally estimated angles were computed in the GETGRAZE SU is initialized to $\Delta r_{grz}$.

If a surface-based duct has been specified, no evaporation duct exists, and the range $r_{flat}$ is greater than the horizon range $r_{hor}$, then a check is made for the possible existence of a skip zone produced by a surface-based duct. If one exists, then the spectrally estimated grazing angles will be included in the interpolation algorithm for those ranges beyond the start of the skip zone. The check for a skip zone is done by performing an iterative loop on the ranges $r_{ray}$ corresponding to the grazing angles in $\psi_{ray}$. For those ranges beyond $r_{hor}$ the maximum difference between successive ranges in $r_{ray}$ is determined according to

$$r_{skip} = \max \left\{ r_{ray,j+1} - r_{ray,j} \right\}; \quad \text{for } j = k-1, k, \ldots, i_{grz}-1,$$

where $k$ is the first element in $r_{ray}$ corresponding to the first range beyond $r_{hor}$. If $r_{skip}$ is greater than 5 km, then a skip zone is assumed to exist and the range $per$ at which spectrally estimated grazing will be included in the interpolation algorithm is set equal to the minimum of $r_{flat}$ or $r_{end}$, where $r_{end}$ is the first range point in $r_{ray}$ just beyond the skip zone. If no skip zone exists, then $per$ is set equal to $r_{max}$. Next, the following steps 1 through 3 are performed for each PE range step $i$, indexed from 1 to $i_{PE}$.

1. For range $r$ less than $r_{hor}$ steps 1.a through 1.c are performed; otherwise, the SU proceeds to step 2.

   a. An iterative loop is performed to find $k$, the element in $r_{ray}$ corresponding to the first range point beyond $r_{hor}$.

   b. For $k$ equal to 1 the grazing angle is determined as

   $$\psi_i = \tan^{-1} \left( -\frac{s}{r} \right),$$

   $$s = h_{ref} - y_{ref} + ant_{ht} - \frac{r^2}{2a_{ext}}.$$

   c. For all other values of $k$, the grazing angle is determined as

   $$\psi_i = \max(0, \psi),$$

   $$\psi = \psi_{ray,k-1} + \psi_{ray,k} \left[ \frac{r - r_{ray,k-1}}{r_{ray,k} - r_{ray,k-1}} \right].$$
2. For range $r$ greater than $r_{hor}$, an iterative loop is performed to determine the number of elements $icr$ within array $r_{ray}$ satisfying the condition $r_{md} < r_{ray} < r_{md} + \Delta r_{PE}$, where $r_{md}$ is the range at mid-PE range step. The following steps a through b are then performed.

a. If $icr$ is non-zero, then the indices $jr1$ and $jr2$ are initialized such that ranges $r_{ray_{jr1}}$ through $r_{ray_{jr2}}$ satisfies the condition in step 2 and $jr2 - jr1$ equals $icr$. If $r_{ray_{jr2}}$ is greater than range $r$, then the grazing angle $\Psi_i$ is interpolated as

$$\Psi_i = \psi_{ray_j} + \psi_{ray_{j+1}} \left[ \frac{r - r_{ray_j}}{r_{ray_{j+1}} - r_{ray_j}} \right]$$

where the index $j$ lies between $jr1$ and $jr2$ and is defined such that $r_{ray_j}$ is the nearest range point less than $r$ and $r_{ray_{j+1}}$ is the nearest range point greater than $r$. If $r_{ray_{jr2}}$ is less than $r$, then the grazing angle $\Psi_i$ is averaged according to

$$\Psi_i = \left( \frac{1}{icr} \right) \sum_{j=jr1}^{jr2} \psi_j$$

b. If $icr$ is equal to 0 and $r$ is greater than $peri$ then grazing angle $\Psi_i$ is computed from interpolation of angles $\psi_{PE}$ determined from spectral estimation. If no spectrally estimated angles exist, then $\Psi_i$ is set equal to 0. If an evaporation duct profile has been specified, then $\Psi_i$ is set equal to $\psi_{ray_{grz}}$.

3. Both $r_{md}$ and $r$ are then incremented by $\Delta r_{PE}$.

Once all grazing angles $\Psi$ have been determined, the arrays $\psi_{ray}$ and $\psi_{PE}$ are deallocated and the SU is exited.

Table 38 and Table 39 identify, describe the purpose for, state the units of, and show the computational source for each input and output data element, respectively, of the GRAZE_INT SU.

5.1.16 Interpolate Profile (INTPROF) SU

The purpose of the INTPROF SU is to perform a linear interpolation vertically with height on the refractivity profile, \(\text{ref}_{\text{ref}}\). Interpolation is performed at each PE mesh height point.

In order to interpolate vertically at each PE mesh height, the following iteration is performed. The index \(j\) is determined such that for every \(i\)th PE bin, \(h_t\) is just greater than \(h_{\text{ref}}\) and \(j < n_{\text{lvl}}\). The interpolated profile \(\text{prof}_{\text{int}}\) is then determined from

\[
\text{prof}_{\text{int}} = \text{ref}_{\text{ref}}(j) + \text{con} \left( \text{ref}_{\text{ref}}(j) - \text{ref}_{\text{ref}}(j-1) \right) \frac{h_t(j) - h_{\text{ref}}(j-1)}{h_{\text{ref}}(j) - h_{\text{ref}}(j-1)}; \quad i = 1,2,3,...n_{\text{fit}},
\]

where the array \(ht\) and constant \(\text{con}\) have been determined in the APMINIT CSC.

Table 40 and Table 41 identify, describe the purpose for, state the units of, and show the computational source for each input and output data element, respectively, of the INTPROF SU.

5.1.17 PE Initialization (PEINIT) SU

The purpose of the PEINIT SU is to initialize all variables used in the PE model for subsequent calls to the PESTEP SU.

Upon entering the SU, several variables are initialized. The following PE transform variables are computed – the angle (or p-space) mesh size, \( \Delta p \); the Fourier transform normalization constant, \( f_{\text{norm}} \); the angle bin width, \( \Delta \theta \), and various transform size factors:

\[
\Delta p = \frac{\pi}{z_{\text{max}}}, \quad f_{\text{norm}} = \frac{2}{n_{\text{fft}}}, \quad n_{34} = \sqrt[4]{n_{\text{fft}}},
\]

\[
\Delta \theta = \frac{\Delta p}{k_0}, \quad n_{\text{ml}} = n_{\text{fft}} - 1, \quad n_4 = \sqrt[4]{n_{\text{fft}}},
\]

The ALLARRAY_PE SU is then referenced to allocate and initialize all arrays associated with PE calculations.

Next, the horizon range, \( r_{\text{hor}} \), for 0 receiver height and the tangent angle, \( a_{\text{cut}} \), to the radio horizon are computed:

\[
r_{\text{hor}} = 4121.81198 \sqrt{\text{ant}_{ht}}
\]

\[
a_{\text{cut}} = \tan^{-1}\left( \frac{\text{ant}_{ht}}{r_{\text{hor}}} \right).
\]

A temporary range step variable is computed as

\[
\Delta r = 55.67485 + 3.52969 \times 10^{-3} r_{\text{max}} - 0.01122 \times 10^{-6} r_{\text{max}}^2.
\]

Due to numerical constraints, limits will be imposed on the PE range step as follows. If performing a terrain case, then the PE range step is computed from

\[
\Delta r_{PE} = \text{MAX}\left(\text{MIN}\left(2k_0\Delta z^2_{PE}, 700, \Delta r\right)\right).
\]

If \( r_{\text{fix}} \) (previously determined in the TERINIT SU) is greater than 0, then the temporary range step variable \( r_d \) is given by \( r_d = \frac{r_{\text{fix}}}{\Delta r_{PE}} \), and \( \Delta r_{PE} \) is recomputed according to
The variable $i_{zinc}$ is then initialized to 1.

If no terrain profile is specified, then $\Delta r_{PE}$ is given by

$$\Delta r_{PE} = \text{MAX}(2k_o \Delta z_{PE}^2, \Delta rt, 100),$$

with the variable $i_{zinc}$ initialized to 1 for frequencies greater than 10 GHz, 2 for frequencies greater than 5 GHz, and 3 otherwise.

If the PEINIT SU has been referenced from the GETGRAZE SU, then the PE range step (which in this case will be used for calculation of the grazing angle by spectral estimation) is further modified:

$$\Delta r_{PE} = \text{MAX}(\Delta r_{PE}, 150) - 1.$$

Otherwise, the range step is multiplied by the range step modifier $r_{mult}$.

The number of PE range steps is then computed:

$$i_{PE} = \text{NINT}\left(\frac{r_{max}}{\Delta r_{PE}}\right).$$

If a terrain profile has been specified, the terrain elevations at each PE range step are now interpolated from the user-specified profile and stored in array $tyh$. The array is allocated for size $i_{PE}$, the range $r$ is initialized to 0, and the elements in $tyh$ are determined according to

$$tyh_i = ty_k + s l p_k (r - tx_k); \quad i = 1, 2, ..., i_{PE},$$

where $r$ is $i \Delta r_{PE}$ and the index $k$ is determined such that $tx_k < r \leq tx_{k+1}$.

The filter array, $filt$, for subsequent filtering of the PE field, is given by
\[ \text{filt}_i = \frac{\sqrt{2}}{2} + \frac{\sqrt{2}}{2} \cos \left( i \frac{\pi}{n_{\text{f}}^i} \right); \quad i = 1, 2, \ldots, n_{\text{f}} \]

The PE mesh height array \( h_t \) is next given by

\[ h_{t_i} = i \Delta z_{\text{PE}}; \quad i = 1, 2, \ldots, n_{\text{f}}. \]

Next, the free-space propagator array \( frsp \) is computed for subsequent use in the PESTEP SU. The propagator term is computed at each PE angle, or p-space, mesh point using the wide-angle propagator. A filter, or attenuation function (frequently called “window”), is then applied to the upper \( \frac{1}{4} \) of the array corresponding to the highest \( \frac{1}{4} \) of the maximum propagation angle.

The complex free-space propagator phase array \( frsp \) is given by

\[ frsp_j = f_{\text{norm}} e^{i \Delta z_{\text{PE}} \left( \frac{k_0^2 - (j \Delta p)^2}{2} \right)}; \quad j = 0, 1, 2, \ldots, n_{\text{f}}. \]

where \( i \) is the imaginary number \( \sqrt{-1} \). The upper \( \frac{1}{4} \) of the free-space propagator array is filtered by a cosine-tapered (Tukey) filter array, \( \text{filt} \) according to

\[ frsp_j = \text{filt}_{j-n_{\text{f}}^34} \cdot frsp_j; \quad j = n_{\text{f}}^34, n_{\text{f}}^34 + 1, n_{\text{f}}^34 + 2, \ldots, n_{\text{f}}. \]

If a simple environmental case has been specified with no terrain and a range-independent refractivity profile, then the INTPROF SU is referenced for interpolation of the refractivity at every PE mesh point. The z-space propagator array \( envpr \) is then computed from

\[ envpr_j = e^{i \Delta z_{\text{PE}} \text{profint}_j}; \quad j = 0, 1, 2, \ldots, n_{\text{f}}. \]

where \( i \) is the imaginary number \( \sqrt{-1} \) and \( \text{profint} \) is the sampled profile obtained from the INTPROF SU. The upper \( \frac{1}{4} \) of \( envpr \) is filtered by a cosine-tapered (Tukey) filter array, \( \text{filt} \), according to

\[ envpr_j = \text{filt}_{j-n_{\text{f}}^34} \cdot envpr_j; \quad \text{for } j = n_{\text{f}}^34, n_{\text{f}}^34 + 1, n_{\text{f}}^34 + 2, \ldots, n_{\text{f}}. \]

Finally, the XYINIT SU is referenced to determine the initial PE solution and the SU is exited.
Table 42 and Table 43 identify, describe the purpose for, state the units of, and show the computational source for each input and output data element, respectively, of the PEINIT SU.

5.1.18 Profile Reference (PROFREF) SU

The purpose of the PROFREF SU is to adjust the current refractivity profile so that it is relative to a reference height, $y_{ref}$. The reference height is initially the minimum height of the terrain profile. Upon subsequent calls from the PESTEP SU, the refractivity profile is adjusted by the local ground height at each PE range step.

The reference height $y_{ref}$, depending on the value of $i_{flag}$, can be either $h_{minter}$ or the local ground height above $h_{minter}$. If $i_{flag}$ is 0, the profile arrays $refref$ and $href$ will be relative to $h_{minter}$ and will also be used to initialize $refdum$ and $htdum$. If $i_{flag}$ is 1, then the profile arrays $refref$ and $href$ will be referenced to the local ground height. The parameter $h_{minter}$ is the reference height for internal calculations in the APM CSCI of the complex field $U$. Both arrays $refdum$ and $htdum$ are dummy arrays containing refractivity values and height values, respectively, for the currently interpolated profile.

The determination of $refref$ and $href$ proceeds as follows. First, the index $nlvl$ is initialized to the number of refractivity levels, $lvcpl$, in $refdum$ and $htdum$; and $refref$ and $href$ are initialized to zero. Next, a test is made to determine whether the absolute value of the reference height $y_{ref}$ is greater than $10^{-3}$ (i.e., is $y_{ref}$ greater than approximately 0). If $y_{ref}$ is approximately zero, the elements of $refref$ are set equal to the corresponding M-unit values of $refdum$ and the elements of $href$ are set equal to the corresponding height values of $htdum$ and the SU is exited.

For the case when $y_{ref}$ is not zero, the following calculations are made. First, the flag $ibmsl$ and the index $j$ are set equal to zero and minus one, respectively. Then, $y_{ref}$ is tested to determine if it is below mean sea level. If so, $ibmsl$ and $j$ are set equal to one and zero, respectively. If $y_{ref}$ is not below mean sea level, then the refractivity profile level at which $y_{ref}$ is just above is determined. The index $j$ is determined such that $y_{ref} \leq htdum_{j+1}$ and $y_{ref} > htdum_j$. 
The refractivity at \( y_{\text{ref}} \) is now computed from

\[
rmu = \text{refdum}_j + \left( \text{refdum}_{j+1} - \text{refdum}_j \right) \frac{y_{\text{ref}} - \text{htdum}}{\text{htdum}_{j+1} - \text{htdum}_j}.
\]

If \( y_{\text{ref}} \) falls below mean sea level and the extrapolation flag \( i_{\text{extra}} \) is zero, then \( rmu \) is given by

\[
rmu = \text{refdum}_j + 0.118 \frac{y_{\text{ref}} - \text{htdum}}{\text{htdum}_{j+1} - \text{htdum}_j}.
\]

The first element in \( \text{refref} \) and \( \text{href} \) is now set equal to \( rmu \) and 0, respectively. The number of refractivity levels in the arrays is now \( l_{\text{new}} = n_{\text{lvl}} - j \) and the remainder of the current refractivity profile is adjusted in height and stored in \( \text{refref} \) and \( \text{href} \) according to

\[
\text{refref}_i = \text{refdum}_k \\
\text{href}_i = \text{htdum}_k - y_{\text{ref}}; \quad i = 1, 2, 3, \ldots, l_{\text{new}},
\]

where the index \( k \) is initialized to \( j+1 \) and is incremented by one with each iteration of \( i \). The variable \( n_{\text{lvl}} \), indicating the number of levels in the newly created profile, is now set to \( l_{\text{new}} \).

Finally, if \( i_{\text{flag}} \) equals zero, then \( \text{lvelp} \) is set equal to \( n_{\text{lvl}} \) and \( \text{refref} \) and \( \text{href} \) are used to initialize \( \text{refdum} \) and \( \text{htdum} \), respectively, before exiting.

Table 44 and Table 45 identify, describe the purpose for, state the units of, and show the computational source for each input and output data element, respectively, of the PROFREF SU.

5.1.19 RD Trace (RDTRACE) SU

The purpose of the RDTRACE SU is to perform ray traces of many rays launched within an angle of ±4°. All angles from rays striking the surface are then sorted and stored for subsequent interpolation in the GRAZE_INT SU.

Upon entering the SU, four in-line ray trace functions are defined for general parameters $a$, $b$, $c$, and $g_{rd}$: RADA1, AP, RP, and HP. These function definitions are identical to those given in section 5.1.14.

Rays are traced with different angular increments at varying intervals. Angular increments are determined such that 1500 rays will be traced between the angular interval ±0.5°, 1000 rays will be traced with launch angles between $|0.5°|$ and $|\theta|$, and 500
rays will be traced for angles between $|\theta|$ and $|\vartheta_{\text{max}}|$. The angular increments are computed as

\[
a_{\text{inc}1} = \frac{\theta_t}{1500}, \quad a_{\text{inc}2} = \frac{\theta_t}{500}, \quad a_{\text{inc}3} = \frac{\vartheta_{\text{max}} - \theta_t}{250},
\]

where $\theta_t$ is $1^\circ$ for $i_{\text{hybrid}}$ equal to 1 and $1.5^\circ$ otherwise. The maximum number of rays to trace, $n_{\text{ray}}$, is then initialized to a large value of 10 times the amount specified above.

Next, the grazing angle array $\psi_{\text{ray}}$ is allocated and initialized with the first element set equal to $\frac{\pi}{2}$. The height of the terrain $y_t$ at the current traced range step is initialized to 0, or $tyh_1$ if a terrain profile has been specified ($f_{\text{ter}}$='true.'). The number of grazing angles $i_{\text{grz}}$ and the launch angle $a_{\text{launch}}$ are initialized to 0 and $-\vartheta_{\text{max}}$, respectively. A DO loop is now implemented where the following steps 1 through 4 are performed an $n_{\text{ray}}$ number of times.

1. At the start of the ray trace, the current local angle ($a_0$), range ($r_0$), height ($h_0$), and refractive gradient index ($j$) are initialized to $a_{\text{launch}}$, 0, $ant_{\text{ref}}$, and $i_{\text{start1}}$, respectively. The terrain slope $t_{\text{slope}}$ of the terrain segment at the current traced range is also initialized to 0.

2. If the antenna height $ant_{\text{ref}}$ is at an inflection point within the refractivity profile, then the following steps 2.a through 2.c are performed, otherwise the current range to trace to, $r_o$, is initialized to 0 and the SU proceeds with step 3.

   a. If $a_0$ is near zero (i.e., $|a_0|$ is less than $10^{-6}$) and no terrain has been specified ($f_{\text{ter}}$='false.'), then the grazing angle and range stored is 0 and $r_{\text{max}}$, respectively. The counter $i_{\text{grz}}$ is incremented by 1, the launch angle is incremented by $a_{\text{inc}1}$, and the SU then repeats steps 1 through 4.

   b. If $a_0$ is near zero and a terrain profile has been specified, then a check is made to determine if the ray intersects a segment of the terrain profile downrange. If so, the range at the point of reflection $r_1$ and the grazing angle are computed as
\[ h = \frac{h_0 - tyh_{k-1}}{tyh_k - tyh_{k-1}} \]

\[ r_1 = [(k - 1) + h] \Delta r_{PE} \]

\[ \psi = \tan^{-1}\left( \frac{tyh_k - tyh_{k-1}}{\Delta r_{PE}} \right) \]

where \( k \) is determined such that \( tyh_{k-1} < h_0 < tyh_k \). The reflection range and grazing angle are then stored, the counter \( i_{grz} \) is incremented by 1, and the launch angle is incremented by \( a_{inc} \). The SU then repeats steps 1 through 4.

c. If \( a_0 \) is less than 0, the index \( j \) is decremented by 1 and the SU proceeds with step 3.

3. A loop is now begun to trace a ray starting with launch angle \( a_{launch} \) to every PE range step. The current range to trace to, \( r_0 \), is incremented by \( \Delta r_{PE} \) and the following steps 3.a through 3.h are performed until one of the following conditions are met: \( r_0 \) reaches \( r_{lim} \), \( h_0 \) reaches \( h_{lim} \), or the difference in reflection range between consecutive grazing angles is less than \( 10^{-3} \). All references to the index \( i \) in the steps below refer to the index in this loop varying from 1 to the number of PE range steps, \( i_{PE} \).

a. The range \( r_1 \) at the end of the range step and the refractive gradient \( g_{rd} \) within the current range step are initialized to \( r_0 \) and \( grdum \), respectively. The propagation angle \( a_1 \) at the end of the range step is computed by \( \text{AP}(a_0, r_1 - r_0) \).

b. If \( |a_0| \) is less than \( 10^\circ \), then if \( a_0 \) and \( a_1 \) differ in sign, \( a_1 \) is set equal to 0 and \( r_1 \) is computed from \( \text{RP}(r_0, a_1 - a_0) \). The height of the ray at the end of the range step is next computed by \( \text{HP}(h_0, a_1, a_0) \). If \( |a_0| \) is greater than \( 10^\circ \), then \( a_1 \) is set equal to \( a_0 \) and \( h_1 \) is computed as

\[ h_1 = h_0 + (r_1 - r_0) \tan^{-1}(a_1) - \frac{(r_1 - r_0)^2}{twoka} \]

where \( twoka \) is determined in the GET_K SU.

c. Once \( r_1, h_1, \) and \( a_1 \) have been computed, it must be determined if the height of the ray has fallen below the elevation height of the terrain at the current range step. The following steps 3.c.i through 3.c.iii are performed if a terrain profile has been specified. Otherwise, the SU proceeds with step 3.d.

i. The height \( h_{ter} \) of the terrain at range \( r_1 \) is computed as
\[ t_{\text{slope}} = \frac{tyh_i - tyh_{i-1}}{\Delta r_{PE}}, \]
\[ h_{\text{ter}} = tyh_{i-1} + \left[ r_i - (i-1)\Delta r_{PE} \right] t_{\text{slope}}. \]

ii. If \( h_1 \) is less than \( h_{\text{ters}} \), then the ray has a reflection point and the range and height of reflection is determined by

\[ r_{\text{slope}} = \frac{h_1 - h_0}{r_1 - r_0}, \quad \text{with } r_1 \text{ recomputed as} \]
\[ r_1 = \frac{tyh_{i-1} - h_0 - t_{\text{slope}}(i-1)\Delta r_{PE} + r_{\text{slope}} r_0}{r_{\text{slope}} t_{\text{slope}}}, \]
\[ h_1 = h_0 + r_{\text{slope}}(r_1 - r_0). \]

iii. If a new range \( r_1 \) and height \( h_1 \) has been computed, then if \( |a_0| \) is less than 10°, then \( a_1 \) is recomputed using \( \text{AP}(a_0, r_1-r_0) \). If \( |a_0| \) is greater than 10°, then \( a_1 \) is set equal to \( a_0 \) and \( h_1 \) is recomputed as

\[ h_1 = h_0 + (r_1 - r_0) \text{TAN}^{-1}(a_1) - \left( \frac{r_1 - r_0}{\text{two}k} \right)^2. \]

d. Next, it must be determined if the ray has passed through a refractive layer, in which case the index must be adjusted and the range, height, and angle must be computed at the refractive layer transition. For an upward ray, if \( a_1 \) is positive and \( h_1 \) has reached or surpassed the next height level, then \( a_1, r_1, j, \) and \( h_1 \), are found as follows. First, \( h_1 \) is set equal to \( h_{\text{tdum}}_{j+1}, j \) is increment by 1, and \( a_1 \) and \( r_1 \) are given by

\[ a_1 = \sqrt{\text{RADA}1(a_0, h_1 - h_0)} \]
\[ r_1 = \text{RP}(r_0, a_1 - a_0). \]

e. For a downgoing ray, if \( a_1 \) is less than or equal to 0, and \( h_1 \) is less than \( h_{\text{tdum}}_j \), then \( h_1 \) is set equal to \( h_{\text{tdum}}_j \), and \( j \) is set equal to the maximum of 0 or \( j-1 \). The variables \( a_1 \) and \( r_1 \) are then determined from

\[ a_1 = -\sqrt{\text{RADA}1(a_0, h_1 - h_0)} \]
\[ r_1 = \text{RP}(r_0, a_1 - a_0). \]
f. If the ray has hit the surface and is reflected, which would be the condition for
which the index $j$ is equal to 0, then the grazing angle and the angle of reflection
with respect to the horizontal are computed as

$$
\psi = \tan^{-1}(t_{\text{slope}}) - a_1
$$

$$
a_{\text{ref}} = 2 \tan^{-1}(t_{\text{slope}}) - a_1.
$$

The range $r_1$ and grazing angle are then stored for later use in the GRAZE_INT
SU.

g. In preparation for the next ray trace step, $h_0$ is set equal to $h_1$, $r_0$ is set equal to $r_1,$
and $a_0$ is set equal to $a_{\text{ref}}.$ If $a_0$ is greater than $\sqrt{2}\pi,$ or if $r_1$ has reached $ro,$ then the
current iteration is exited and the SU proceeds to step 3.h; otherwise, steps 3.a
through 3.g are repeated until $r_0$ reaches $ro.$

h. The range $ro$ [to trace to] for the next step is incremented by $\Delta r_{PE}$ and step 3 is
repeated for all range steps.

4. Once a ray has been traced through the entire $i_{PE}$ number of range steps, $a_{\text{launch}}$ is
increased. If $|a_{\text{launch}}|$ is less than 0.5°, the launch angle is increased by $a_{\text{inc1}};$
otherwise, if $|a_{\text{launch}}|$ is less than $\theta_n$ then it is increased by $a_{\text{inc2}}.$ If neither of these
conditions are met, then $a_{\text{launch}}$ is increased by $a_{\text{inc3}}.$ Steps 1 through 4 are repeated
until an $n_{\text{ray}}$ number of rays have been traced.

Finally, the grazing angles are sorted by range and stored in array $\psi_{\text{ray}}$ and the SU
is exited.

Table 46 and Table 47 identify, describe the purpose for, state the units of, and
show the computational source for each input and output data element, respectively, of
the RDTRACE SU.

5.1.20 Refractivity Initialization (REFINIT) SU

The purpose of the REFINIT SU is to check for valid environmental profile inputs and to initialize all refractivity arrays used within one application of APM.
Upon entering, the maximum height $h_{\text{large}}$ at which the refractivity profile is extrapolated is set to $10^6$ meters in a DATA statement. In addition, $i_{\text{error}}$ is initialized to zero.

The environmental data is checked to determine if range-dependent profiles have been specified ($n_{\text{prof}} > 1$). If so, the range of the last profile entered, $rng_{\text{prof}}$, is checked and if it is less than the maximum output range specified, $r_{\text{max}}$, an error message is returned (i.e., $i_{\text{error}}$ is set equal to -12) depending on the value of error flag, $lerr12$, set in the NITES application itself. The SU is then exited; otherwise, if no error occurs, the SU proceeds to the next step.

Next, the REFINIT SU tests for valid refractivity level entries for each profile. Every user-specified profile is tested to make sure the first level in the profile begins with a value of zero height (or less than zero if the first level is below mean sea level). If it does not, $i_{\text{error}}$ is set to -13 and the SU is exited; otherwise, the SU proceeds to the next step.

A test is then made to determine if the last gradient in each profile is negative. If the last gradient in any profile is negative, $i_{\text{error}}$ is set to minus fourteen and the SU is exited; otherwise, an additional refractivity level is extrapolated to height $h_{\text{large}}$ and added to each profile. The additional level is added according to

$$
\begin{align*}
\text{grd}_{ij} &= \frac{\text{refm}_{ij} - \text{refm}_{i,j-1}}{h_{m}-h_{m-1}}, \\
\text{refm}_{ij} &= \text{refm}_{i,j-1} + \text{grd}(h_{m} - h_{m-1}),
\end{align*}
\quad i = 1, 2, 3, \ldots, n_{\text{prof}}
$$

where

$$
\text{grd}_{ij} = \frac{\text{refm}_{i,j-1} - \text{refm}_{i,j-2}}{h_{m}-h_{m-1}}.
$$

The counter for the current profile, $i_{s}$, is now initialized to 1 and the range of the next refractivity profile, $r_{v2}$, is initialized to $rng_{\text{prof}}$. Next, the results of the extrapolation of the first environmental profile (i.e., the profile at range 0) are transferred to dummy arrays, $htdum$ and $reftum$, respectively. The index $lvlep$ is now set equal to $lvlp$. Duplicate levels in the first profile are removed by a reference to the REMDUP SU, and $reftum$ and $htdum$ are adjusted to the minimum terrain height by a reference to the PROFREF SU. The parameter $nvl$, returned from the PROFREF SU, is now the number of height/refractivity levels in the adjusted $htdum$ and $reftum$ arrays.

If troposcatter calculations have been specified ($T_{\text{tropo}} = \text{.true.}$), then the surface refractivity at the transmitter $snr_{\text{tx}}$ is determined by referencing the PROFREF SU to adjust the profile relative to $y_{\text{fre}}$ and initializing $snr_{\text{tx}}$ to $reftx_0$. 

Next, the height and thickness of the highest trapping layer (if one exists), \( h_{\text{trap}} \) and \( h_{\text{thick}} \), respectively, are found relative to \( h_{\text{minter}} \). First, \( h_{\text{trap}} \) and \( h_{\text{thick}} \) are initialized to zero. Then the following steps 1 through 2 are performed for each \( i \)th profile and for each \( j \)th refractivity level.

1. The gradient of the current height/refractivity level \( \text{grd} \) and its height relative to \( h_{\text{minter}} \), \( h_{p1} \), are found from

\[
\text{grd} = \text{refmsl}_{j+i,i} - \text{refmsl}_{j,i},
\]

\[
h_{p1} = \text{hmsl}_{j+i,i} - h_{\text{minter}}.
\]

2. If \( \text{grd} \) is negative and \( h_{p1} \) is greater than \( h_{\text{trap}} \), then \( h_{\text{trap}} \) is set equal to \( h_{p1} \), and \( h_{p0} \) and \( h_{\text{thick}} \) are determined from

\[
h_{p0} = \text{hmsl}_{j,i} - h_{\text{minter}},
\]

\[
h_{\text{thick}} = h_{p1} - h_{p0}.
\]

Next, the index level \( i_{\text{start1}} \) within the refractivity profile of the antenna height \( \text{ant}_{\text{ref}} \) is determined and the gradient array \( \text{grdum} \) is computed as

\[
\text{grdum}_i = 10^{-6} \left( \frac{\text{refdum}_{i+1,i} - \text{refdum}_{i,i}}{\text{htdum}_{i+1,i} - \text{htdum}_{i,i}} \right); \quad i = 0, 1, 2, \ldots, \text{lvl} - 1.
\]

If using the full hybrid mode \( (i_{\text{hybrid}} = 1) \), then the following steps 1 through 4 are performed to build arrays associated with ray optics (RO) calculations. Otherwise, the M-unit value \( \text{rm}_{\text{tx}} \) at the antenna height is determined from

\[
\text{rm}_{\text{tx}} = 10^{-6} \left[ \text{refdum}_{i_{\text{start1}}} + \text{grdum}_{i_{\text{start1}}} 10^{6} \left( \text{ant}_{\text{ref}} - \text{htdum}_{i_{\text{start1}}} \right) \right]
\]

and the SU continues with the procedures following step 4.

1. First, the refractivity and height arrays \( \text{rm} \) and \( \text{zrt} \) are built. All elements in \( \text{zrt} \) are set equal to all elements in \( \text{htdum} \). An additional height level, equal to \( \text{ant}_{\text{ref}} \), is included in \( \text{zrt} \) and the index \( i_{\text{start}} \) is initialized to that height level which corresponds to \( \text{ant}_{\text{ref}} \). Array \( \text{rm} \) is given by

\[
\text{rm}_i = 10^{-6} \text{refdum}_i, \quad i = 1, 2, 3, \ldots, \text{nvl},
\]

with the refractivity level at height \( \text{ant}_{\text{ref}} \) interpolated according to
\[ rm_{i_{\text{start}}} = rm_{i_{\text{start}} + 1} + \left( \frac{an_{\text{ref}} - zrt_{i_{\text{start}}}}{zrt_{i_{\text{start}} + 1} - zrt_{i_{\text{start}} - 1}} \right) \left( \frac{rm_{i_{\text{start}} + 1} - rm_{i_{\text{start}} - 1}}{zrt_{i_{\text{start}} + 1} - zrt_{i_{\text{start}} - 1}} \right). \]

The total number of levels \textit{levels} in \textit{zrt} is reduced by 1 since the highest level is not needed.

2. For the special case when the terrain profile is initially flat, but at non-zero height, the following steps 2.a through 2.d are performed to adjust the refractivity arrays \textit{rm} and \textit{zrt} associated with RO calculations. First, the index \textit{nlevel} is initialized to the number of refractivity levels, \textit{levels}; \textit{y}_{\text{ref}} is initialized to \textit{ty}_1; \textit{ref} and \textit{href} are initialized to zero; and the index \textit{js} is initialized to -1.

a. Next, \textit{js} is determined such that \( zrt_{js} < y_{\text{ref}} \leq zrt_{js+1} \). If a value for \textit{js} is not found such that this condition holds true (i.e., \textit{js} remains at -1), then the SU proceeds with step 2.d.

b. The refractivity at \textit{y}_{\text{ref}} is now computed from

\[ f_{\text{rac}} = \frac{y_{\text{ref}} - zrt_{js}}{zrt_{js+1} - zrt_{js}}, \]

\[ rm_{\text{u}} = rm_{js} + f_{\text{rac}}(rm_{js+1} - rm_{js}). \]

If \( \text{INT}(f_{\text{rac}}) \) is equal to 1, then \textit{js} is set equal to \textit{js}+1. The temporary counter \textit{l}_{\text{new}} is initialized to \textit{nlevel}-\textit{js}.

c. The first element in \textit{ref} and \textit{href} is now set equal to \textit{rm}_{\text{u}} and 0, respectively. The remainder of the current refractivity profile is adjusted in height and stored in \textit{ref} and \textit{href} according to

\[ ref_{j} = rm_{k} \]
\[ href_{j} = zrt_{k} - y_{\text{ref}}; \quad j = 1, 2, 3, \ldots l_{\text{new}}, \]

where the index \( k \) is initialized to \textit{js}+1 at the start and is incremented by one with each iteration of \textit{j}. The variable \textit{levels}, indicating the number of levels in the newly created profile, is now set to \textit{l}_{\text{new}}. \textit{ref} and \textit{href} are now used to initialize \textit{rm} and \textit{zrt}.

d. The variable \textit{i}_{\text{start}} is now reduced by the amount \textit{js}. 
3. The arrays $gr$ and $q$, used in RO and ray-tracing calculations, are determined next. The gradient array $gr$ is given by

$$gr_i = \frac{rm_{i+1} - rm_i}{zr_{i+1} - zr_i}; \quad i = 0, 1, 2, \ldots, \text{levels},$$

The array $q$ is given by

$$q_i = 2(rm_{i+1} - rm_i); \quad i = 0, 1, 2, \ldots, \text{levels}.$$

4. The M-unit value $rm_{tx}$ at the antenna height is now set equal to $rm_{start}$.

Next, the minimum M-unit value $rm_{min}$ of the refractivity at range 0 is determined by searching for the minimum numerical value in array $refdum$ and assigning $rm_{min}$ this value. The maximum M-unit value $rm_{max}$ at or below the antenna height is then determined from

$$rm_{max} = \text{MAX}(10^6 rm_{tx}, refdum_i); \quad i = 0, 1, 2, \ldots, i_{start1}.$$

Both $rm_{min}$ and $rm_{max}$ are then multiplied by $10^{-6}$. If the antenna is within a duct, the flag $l_{duct}$ is set to ‘.true.’, and the critical angle $a_{crit}$ is computed as

$$a_{crit} = \sqrt{2(rm_{tx} - r_{crit})} + 10^{-6},$$

where $r_{crit}$ is the minimum M-unit value in the profile for levels above the height $ant_{ref}$.

Finally, a check is made to determine if an evaporation profile exists. This check is performed only if a range-independent profile has been specified ($n_{prof} = 1$) and if $h_{trap}$ is greater than 0. An evaporation duct is assumed to exist if the height at which $rm_{min}$ occurs is less than 40 meters and if the difference between successive gradients is less than or equal to 0.1. If these two conditions occur, then the flag $l_{evap}$ is set to ‘.true.’.

Table 48 and Table 49 identify, describe the purpose for, state the units of, and show the computational source for each input and output data element, respectively, of the REFINIT SU.

5.1.21 Remove Duplicate Refractivity Levels (REMDUP) SU

The purpose of the REMDUP SU is to remove any duplicate refractivity levels in the current interpolated profile. Adjoining profile levels are checked to see if the heights are within 0.001 meters. If they are, the duplicate level in the profile is removed. This process continues until all profile levels ($lvlep$) have been checked.

Table 50 and Table 51 identify, describe the purpose for, state the units of, and show the computational source for each input and output data element, respectively, of the REMDUP SU.

5.1.22 Terrain Initialization (TERINIT) SU

The purpose of the TERINIT SU is to examine and initialize terrain arrays for subsequent use in PE calculations. It tests for and determines a range increment if it is found that range/height points are provided in fixed range increments. The minimum terrain height is determined, and the entire terrain profile is adjusted in height so that all internal calculations are referenced to this height. This is done in order to maximize the PE transform calculation volume.

First, several variables are initialized. The logical flag, $f_\text{ter}$, used to indicate whether the application at hand is a terrain case, is set equal to ‘.false.’. The integer flag, $i_\text{error}$, that is returned if any errors exist in input data, is set equal to zero. The maximum tangent ray angle, $\alpha_u$, from source to terrain peak along the profile path is set equal to zero. The minimum height of the terrain profile, $h_{\text{minter}}$, is set equal to zero. The transmitting antenna height, $ant_{\text{ref}}$, relative to the reference height $h_{\text{minter}}$ is set equal to $ant_{\text{ht}}$. The maximum terrain height, $h_{\text{termax}}$, along the profile path is set equal to zero. Finally, if the number of terrain points $i_p$ specified is greater than zero, then $f_\text{ter}$ is set equal to ‘.true.’.

If performing a terrain case ($f_\text{ter} = \text{.true.}$), the following steps (1 through 9) are performed; otherwise, the SU proceeds to step 10.

1. First, all terrain range points are checked in array $ter_x$ to ensure they are steadily increasing. If they are not, the error flag $i_{\text{error}}$ is set equal to -17 and the SU is exited. Otherwise, the SU proceeds to step 2.
2. Next, a test is made to determine whether the first range value is zero. If it is not, the error flag \( i_{\text{error}} \) is set equal to -18 and the SU is exited. Otherwise, the SU proceeds to step 4.

3. Next, a test is made to determine if the last range point within the terrain profile meets or exceeds \( r_{\text{max}} \). If the logical flag \( l_{\text{err6}} \) is ‘true.’ and if the condition \( \text{terx}_{i_p} < r_{\text{max}} \) is met, then \( i_{\text{error}} \) is set equal to -6 and the SU is exited; otherwise, the SU proceeds to step 4.

4. A check is now made to determine if the specified terrain range points are spaced at fixed increments. In this procedure, three variables, \( r_{\text{dif1}} \), \( r_{\text{frac}} \), and \( r_{\text{difsum}} \) are initialized to \( \text{terx}_2-\text{terx}_1 \), zero, and \( r_{\text{dif1}} \), respectively. The variable \( r_{\text{dif1}} \) is the difference between adjacent terrain point ranges. The variable \( r_{\text{frac}} \) is the ratio between adjacent terrain point differences. The variable \( r_{\text{difsum}} \) is the running sum of adjacent terrain point differences. The final value for \( r_{\text{difsum}} \) and maximum \( r_{\text{frac}} \) are determined as

\[
rdif_2 = \text{MAX}\left(0^{-3}, \, \text{terx}_{i+1} - \text{terx}_i \right) ; \, \, \, i = 2, 3, \ldots, i_{p} - 1
\]

\[
r_{\text{frac}} = \frac{rdif_2}{rdif_1}
\]

\[
r_{\text{difsum}} = r_{\text{difsum}} + rdif_2
\]

where \( rdif_1 \) is set equal to the previous value of \( rdif_2 \) before each subsequent calculation of a new \( rdif_2 \), and \( r_{\text{frac}} \) is the maximum of all ratios computed.

5. If it is determined that the terrain points are spaced at fixed range increments, then the range spacing \( r_{\text{fix}} \) is set to this increment. Assuming that the range points are not equally spaced, \( r_{\text{fix}} \) is initially set equal to zero. If the value of \( r_{\text{frac}} \) is less than 1.05, then \( r_{\text{fix}} \) is determined from

\[
r_{\text{fix}} = \text{NINT} \left( \frac{r_{\text{difsum}}}{i_{p} - 1} \right).
\]

6. The minimum height \( h_{\text{minter}} \) of the terrain profile is now found and the entire terrain profile is adjusted by \( h_{\text{minter}} \) such that this is the new zero reference. The adjusted terrain profile is stored in arrays \( tx \) and \( ty \) (i.e., \( ty = \text{tery} - h_{\text{minter}} \) for all elements in \( \text{tery} \)). Next, the maximum height \( h_{\text{termax}} \) of the terrain is also obtained from \( \text{tery} \). If \( h_{\text{termax}} \) exceeds \( h_{\text{max}} \), then \( i_{\text{error}} \) is set equal to -8 and the SU is exited. Otherwise, the SU proceeds with step 7.
7. An extra point is added to the arrays \( tx \) and \( ty \). If \( tx_{ip} \) is less than \( r_{max} \), then \( tx_{i_{pa}} \) is set equal to \( r_{max} \) times 1.1. The input index \( i_{pa} \) is the number of terrain points used internally in arrays \( tx \) and \( ty \). If \( tx_{ip} \) is greater or equal to \( r_{max} \), then \( tx_{i_{pa}} \) is set equal to \( tx_{ip} \) times 1.1. Finally, the array element \( ty_{i_{pa}} \) is set equal to \( ty_{ip} \).

8. The variable \( ant_{ref} \) is set equal to \( ant_{ht} \) plus \( ty_{1} \). Next, the array of terrain slopes, \( slp \), and the maximum tangent ray angle, \( \alpha_u \), from the source to the terrain peak along the profile path are found as follows. The slope, \( slp_i \), for each \( i^{th} \) terrain segment is given by

\[
slp_i = \frac{ty_{i+1} - ty_i}{\text{MAX}(tx_{i+1} - tx_i, 10^{-5})} \; ; \; i = 1, 2, 3, \ldots, i_{pa} - 1.
\]

If the current slope is greater than the slope tolerance of \( 10^{-5} \) then it is assumed that the terrain profile is no longer flat at the current range and the variable \( r_{flat} \) is set equal to \( tx_i \). Next, if the value of \( ty_i \) is greater than \( ant_{ref} \), then the maximum tangent angle \( \alpha_u \) from the source to each terrain point is calculated as

\[
\alpha_u = \text{MAX} \left[ \tan^{-1} \left( \frac{ty_i - ant_{ref}}{tx_i} \right) \right] \; ; \; i = 1, 2, 3, \ldots, i_{pa} - 1.
\]

After \( \alpha_u \) is determined, 0.5° is added to its value.

9. If rough surface calculations are required \( (ruf = \text{.true.}) \) then a search of the specified ground types is performed to check if types are other than sea water. If ground types are other than sea water for the entire range of the terrain profile then rough surface calculations are turned off by setting \( ruf \) equal to \( \text{.false.} \) (the APM CSCI only accounts for rough sea surface effects).

10. Before exiting, the minimum height \( h_{mref} \) relative to \( h_{minter} \) is found from the difference between the minimum specified output height \( h_{min} \) and \( h_{minter} \). The maximum height limit \( h_{lim} \) relative to \( h_{minter} \) is given by the difference between \( h_{max} \) and \( h_{minter} \). If the antenna height \( ant_{ref} \) is greater than \( h_{lim} \), the error code \( i_{error} \) is set to -9.

5.1.23 Trace to Output Range (TRACE_ROUT) SU

The purpose of the TRACE_ROUT SU is to trace a single ray, whose launch angle is specified by the calling routine, to each output range. The height of this ray is stored at each output range for subsequent proper indexing and accessing of the appropriate sub-models.

Upon entering the SU, four in-line ray trace functions are defined for general parameters $a$, $b$, $c$, and $g_{rd}$: RADA1, AP, RP, and HP. These function definitions are identical to those given in section 5.1.14.

Next, the propagation angle, range, and height at the beginning of the range step, $a_0$, $r_0$, $h_0$, respectively, are initialized to $a_s$, $r_s$, and $h_s$ – the angle, range and height specified by the calling SU. The profile index $j$ is also initialized to $j_s$ from the calling SU. The index $j_r$ is determined such that $rng_{out_{j_r}}$ is the first range point greater than $r_0$. The array $h_{array}$, containing the heights of the traced ray at each output range, is then set equal to 0 for elements 1 through $j_r$. The following steps 1 through 2 are performed for each output range step $i$ from $j_r$ to $n_{out}$.

1. First, $h_{array_{j_r}}$ is set equal to zero and the variable $ro$ is set equal to $rng_{out_{j_r}}$. Next, the following steps 1.a through 1.d are performed until $r_0$ has reached $ro$ or $h_0$ has reached $ht_{lim}$.

   a. First, the range, $r_1$, at the end of the ray trace segment is set equal to $ro$. Then the current gradient $g_{rd}$ is set equal to $grdum_{j}$. The angle, $a_1$, at the end of the ray trace segment is found from AP($a_0$, $r_1$-$r_0$).

   b. If $a_1$ is of the opposite sign as $a_0$, then $a_1$ is set equal to zero and $r_1$ is given by RP($r_0$, $a_1$-$a_0$). $h_1$ is then given by HP($h_0$, $a_1$, $a_0$).
c. Now the value of \( h_1 \) is tested. If the value of \( h_1 \) is greater than or equal to \( h_{tdum_{j+1}} \) then \( h_1 \) is set equal to the minimum of \( h_{lim} \) or \( h_{tdum_{j+1}} \), and \( a_1, r_1 \) and the index \( j \) are re-computed as

\[
\begin{align*}
a_1 &= \sqrt{\text{RADA} \ 1(a_0, h_1 - h_0)} \\
r_1 &= \text{RP}(r_0, a_1 - a_0) \\
j &= \text{MIN}(lvlep, j + 1).
\end{align*}
\]

\[\]

\[\]

d. If \( h_1 \) is less than \( h_{tdum_{j+1}} \) but greater than \( h_{lim} \), then \( h_1 \) is set equal to \( h_{lim} \) and \( a_1 \) and \( r_1 \) are re-computed as in step 1.c above. The angle, range, and height variables \( a_0, r_0, \) and \( h_0 \) are now set equal to \( a_1, r_1, \) and \( h_1 \) in preparation for the next step. Steps 1.a through 1.d are repeated until \( r_0 \geq ro \).

2. Once \( r_0 \) has reached \( ro \), \( h_{array_{jr}} \) is then set equal to \( h_0 \). The index \( jr \) is then incremented by 1 and steps 1 through 2 are repeated for all output range steps or until \( h_0 \) has reached \( h_{lim} \).

Finally, if the traced ray has reached \( h_{lim} \) at a range before \( r_{max} \), then \( h_{array} \) is set equal to \( h_{lim} \) for elements from \( jr \) to \( n_{rout} \) with the index \( i_{hmx} \), indicating the element in \( h_{array} \) where this occurs, set equal to \( jr \).

Table 54 and Table 55 identify, describe the purpose for, state the units of, and show the computational source for each input and output data element, respectively, of the TRACE_ROUT SU.

5.1.24 Troposcatter Initialization (TROPOINIT) SU

The purpose of the TROPOINIT SU is to initialize all variables and arrays needed for subsequent troposcatter calculations. The tangent range and tangent angle are determined from the source and the tangent range and tangent angles are determined for all receiver heights and stored in arrays.

Upon entering the SU, the array $\vartheta_1t$ is allocated for size $i_{PE}$ and initialized to 0. Next, the GET_K SU is referenced to determine the effective earth radius factor $a_{ek}$ based on a ray launched at the critical angle traced to $ht_{lim}$. The array $\vartheta_0$, containing angles used in determining the common volume scattering angle is then determined from

$$\vartheta_0_{i} = \frac{\text{rngout}_{i}}{a_{ek}}; \quad \text{for } i = 1, 2, 3, ..., n_{\text{rout}} .$$

A constant needed in the troposcatter calculation, $r_{f}$, is determined from 0.0419 times the frequency $f_{\text{MHz}}$. A second constant needed in the troposcatter calculation, $r_{t1}$, is found from $r_{f}$ times the adjusted transmitting antenna height $ant_{ref}$. Next, the tangent angle from the source, $\vartheta_1s$, for smooth surface is computed from

$$\vartheta_1s = \sqrt{twoka * ant_{ref}} / a_{ek} .$$

The variable $\alpha_d$ is determined from

$$\alpha_d = 20 \ \text{LOG}_{10}(f(\alpha_d))$$

$$\alpha_d = \vartheta_1s + 10^{-6} ,$$

where $\alpha_d$ represents the lowest direct ray angle in the RO region, and $f(\alpha_d)$ is the antenna pattern factor, obtained from referencing the ANTPAT SU, for the direct angle.

The minimum range, $r_{\text{hor1}}$, at which the diffraction field solutions are applicable and the intermediate region ends is determined for smooth surface and zero receiver height. The variable $r_{\text{hor1}}$ is given by
\[ r_{\text{hor1}} = \sqrt{r_{\text{woka}} \cdot ant_{\text{ref}}} + 230200.0 \left( \frac{e_k^2}{f_{\text{MHz}}} \right) \],

where \( e_k \) is the effective Earth’s radius factor value obtained from the GET_K SU.

Next, the tangent ranges and angles for all output receiver heights are computed and stored in arrays \( d2s \) and \( \vartheta2s \), respectively. The minimum ranges at which diffraction field solutions are applicable (for smooth surface) for all output receiver heights are determined and stored in array \( rdt \). Height differences between \( ant_{\text{ref}} \) and each output receiver height are also computed and stored in \( adif \). These arrays are given by

\[ d2s_i = \sqrt{2a_{ek} z_{out_i}}, \]
\[ \vartheta2s_i = \frac{d2s_i}{a_{ek}}, \quad i = 0, 1, 2, \ldots, n_{zout} \]
\[ rdt_i = r_{\text{hor1}} + d2s_i \]
\[ adif_i = ant_{\text{ref}} - z_{out_i}, \]

where the computation is performed for each \( i \)th output receiver height \( z_{out_i} \), provided \( z_{out_i} \) is greater than or equal to 0, and \( i \) ranges from 1 to \( n_{zout} \).

If \( f_{\text{ref}} \) is ‘true.’, then the tangent angles \( \vartheta_{lt} \) from the source at every PE range is determined as

\[ \vartheta_{lt} = \frac{ant_{\text{ref}} - tyh_{j}}{j \Delta r_{PE}} + \frac{j \Delta r_{PE}}{2a_{ek}}, \quad j = 1, 2, 3, \ldots, i_{PE} . \]

The index counter \( j_{t2} \) (used in the TROPOSCAT SU) is initialized 1. Finally, the troposcatter loss term \( tlst_{wr} \), used in the TROPOSCAT SU is given by

\[ tlst_{wr} = 54.9 + 30 \ \text{LOG}_{10}(f_{\text{MHz}}) - \alpha_{ld} . \]

Table 56 and Table 57 identify, describe the purpose for, state the units of, and show the computational source for each input and output data element, respectively, of the TROPOINIT SU.

5.1.25 Starter Field Initialization (XYINIT) SU

The purpose of the XYINIT SU is to calculate the complex PE solution at range zero.
Upon entering this SU, several constant terms which will be employed over the entire PE mesh are calculated. The PE mesh is defined by the number of points in the mesh, \( n_{\text{fft}} \), and by the mesh size \( \Delta \rho \). The constant terms include: (1) the angle difference between mesh points in p-space \( \Delta \theta \); (2) a height-gain value at the source (transmitter) \( \text{antko} \); and (3) the normalization factor \( s_{\text{gain}} \) used in the determination of the complex array containing the field \( U \). The normalization factor \( s_{\text{gain}} \) is given by

\[
s_{\text{gain}} = \frac{\sqrt{\lambda}}{z_{\text{max}}}.
\]

The height-gain value \( \text{antko} \) at the source (transmitter) is given by

\[
\text{antko} = k_o \text{ant}_{\text{ht}}
\]

where \( \text{ant}_{\text{ht}} \) is the transmitting antenna height above the local ground in meters.

The complex PE solution \( U \) is determined from the antenna pattern factors, elevation angle, and normalization factor according to

\[
U_j = c_a s_{\text{gain}} \left[ f(\alpha_d)e^{-ip_j \text{antko}} - f(-\alpha_d)e^{ip_j \text{antko}} \right]; \quad \text{H pol}
\]

\[
U_j = c_a s_{\text{gain}} \left[ f(\alpha_d)e^{-ip_j \text{antko}} + f(-\alpha_d)e^{ip_j \text{antko}} \right]; \quad \text{V pol}
\]

\[
\alpha_d = \sin^{-1}(p_j),
\]

\[
c_a = \left(1 - p_j^2\right)^{-1/4}
\]

where \( p_j = j \Delta \theta \) and the antenna pattern factors \( f(\alpha_d) \) for the direct path and \( f(-\alpha_d) \) for the reflected path are determined by referencing the ANTPAT SU. The index \( j \) varies from 0 to \( n_{\text{fft}} \).

Next, the upper \( 1/4 \) of the field is filtered. A cosine-tapered (Tukey) filter array \( \text{filt} \) is used for this purpose. The filtered PE field \( U \) is given by

\[
U_j = \text{filt}_{j-n_{34}} U_j; \quad j = n_{34}, n_{34} + 1, n_{34} + 2, \ldots, n_{\text{fft}}.
\]

Finally, the DRST SU is referenced for both the real and imaginary components to transform the complex PE field to z-space before exiting the SU.

Table 58 and Table 59 identify, describe the purpose for, state the units of, and show the computational source for each input and output data element, respectively, of the XYINIT SU.

5.2 ADVANCED PROPAGATION MODEL STEP (APMSTEP) CSC

The purpose of the APMSTEP SU is to advance the entire APM CSCI algorithm one output range step, referencing various SUs to calculate the propagation loss at the current output range.

Upon entering the APMSTEP SU, the current output range \( r_{out} \) is updated, the gaseous absorption loss, \( \text{gas}_{loss} \), in dB and all mpfl array integer indices for the various calculation regions are initialized. The PESTEP SU is then referenced to determine all propagation loss values within the PE calculation region. If the PE-only option is specified (\( \text{PEflag} = \text{.true.} \)) then mpfl is returned with integer indices \( j_{ps} \) and \( j_{pe} \) corresponding to the start and end, respectively, of propagation factor and loss values within mpfl. Otherwise, the SU proceeds with the following steps 1 through 3.

1. If APM is executing using the airborne model (\( i_{hybrid} = 0 \)) then the starting index \( j_{as} \) for the airborne region is initialized to the maximum of 0 and \( i_{2g} \) plus \( i_p \). The ending
index within this region $j_{ae}$ is determined by performing an iterative search to find the index at which the first occurrence of $z_{outj}$ is greater than $htfe_{stip}$. $j_{ae}$ is then set equal to the index $j$. The AIRBORNE SU is then referenced to compute the loss for the lower FE region, provided $j_{as}$ is less then $j_{ae}$. Upon returning, $j_{start}$ is then set equal to $j_{as}$, $j_{as}$ is set equal to $j_{pe}+1$, $j_{ae}$ is set equal to $n_{zout}$, and the AIRBORNE SU is again referenced to compute loss for the upper FE region. The SU then proceeds with step 3.

2. If APM is executing under the full hybrid mode ($i_{hybrid} = 1$) and the current output range is less than the range at which the XO region begins ($r_{out} < r_{atz}$), the following steps 2.a and 2.b are performed.

   a. The starting and ending $mpfl$ array indices for FE calculations, $j_{fs}$ and $j_{fe}$, respectively, are determined. For ranges less than 2.5 km, $j_{fs}$ is set equal to the maximum of 0 and $izg$ plus $io$, and $j_{fe}$ is set equal to $n_{zout}$. For ranges greater than 2.5 km, $j_{fs}$ is set equal to the maximum of $j_{pe}+1$, or $j+1$, where $j$ is the first occurrence of $z_{outj}$ that is greater than $htfe_{stip}$ (the output height index which corresponds to the height just above the FE 5° angle limit). The ending index $j_{fe}$ is set equal to $n_{zout}$. The FEM SU is then referenced and propagation factor and loss values within the FE region are computed and returned in $mpfl$.

   b. If the current output range is greater than 2.5 km, then the starting and ending $mpfl$ array indices for RO calculations, $j_{rs}$ and $j_{re}$, respectively, are determined. These indices are based on the values of $j_{ps}, j_{pec}, j_{fs},$ and $j_{fe}$ such that at every range step, $j_{rs}$ will always be greater than the ending index of the PE region ($j_{pe}$) and $j_{re}$ will be less than the starting index of the FE region ($j_{fe}$). The ROLOSS SU is then referenced, and propagation factor and loss values within the RO region are computed and returned in $mpfl$.

3. Once the various propagation factor and loss within the various regions have been calculated, the ending index $j_{end}$ of valid values within $mpfl$ is given by the maximum of $j_{pe}, j_{fe}, j_{re},$ and $j_{ae}$.

   Upon exiting, if the final output range step has been reached, the integer counter $j_{tz}$, associated with troposcatter calculations, is initialized to 1.

   Table 60 and Table 61 identify, describe the purpose for, state the units of, and show the computational source for each input and output data element, respectively, of the APMSTEP SU.

5.2.1 Airborne Hybrid Model (AIRBORNE) SU

The purpose of the AIRBORNE SU is to determine propagation factor and loss based on flat-earth calculations for the direct ray path only for regions above and below the PE maximum propagation angle.

Upon entering the SU, the square of the current range, \( r_{sq} \), is initialized to \( rsqrd_{isp} \). Next, the earth curvature height correction factor \( r_{sqk} \) is initialized according to the calculation region:

\[
\begin{align*}
\text{above PE region:} & \quad r_{sqk} = \frac{r_{sq}}{twoka} \\
\text{below PE region:} & \quad r_{sqk} = \frac{r_{sq}}{twoka_{down}}
\end{align*}
\]

The following steps 1 through 2 are performed for all heights within array \( zoutma \) with index \( j \) varying from \( j_{as} \) to \( j_{ae} \).

1. First, the direct ray angle is computed as

\[
\alpha = \tan^{-1} \left( \frac{zoutma_j - r_{sqk}}{r_{out}} \right).
\]

2. Next, if the direct ray \( \alpha \) is greater than the tangent angle \( \alpha_{ter} \) produced from the antenna height to the current terrain height, or the calculations are for the upper PE region, then steps 2.a through 2.d are performed.

   a. The ANTPAT SU is referenced to obtain the antenna pattern factor \( f(\alpha) \) for the direct ray.
b. The path length of the direct ray is then computed:

\[ r_i = \sqrt{(z_{outma} - r_{sqk})^2 + r_{sq}}. \]

c. The propagation factor \((F_{dB})\) and loss \((L)\) are then computed from

\[
L = 20 \log_{10}(r_i) + pl_{cnst} - 20 \log_{10}\left(\max\left(f(\alpha), 10^{-13}\right)\right) + r_i gas_{att}
\]

\[
F_{dB} = 20 \log_{10}(r_i) + pl_{cnst} - L.
\]

Note that \(F_{dB}\) above is actually 20 times the logarithm of the propagation factor \(F\) as defined in most text books.

d. Lastly, \(L\) and \(F_{dB}\) are multiplied by 10 and rounded to the nearest integer then stored in array \(mpfl\). Once the loss has been computed for all heights, the SU is then exited.

Table 62 and Table 63 identify, describe the purpose for, state the units of, and show the computational source for each input and output data element, respectively, of the AIRBORNE SU.

</table>
5.2.2 Calculate Propagation Loss (CALCLOS SU)

The purpose of the CALCLOS SU is to determine the propagation factor and loss at each output height point at the current output range.

Upon entering the SU, several variables are initialized. The output range, $r_{out}$, is updated based on the current range step $istp$. The height of the terrain at the current and last ranges, $y_{ch}$ and $y_{lh}$, respectively, are determined relative to the reference height, $hm_{ref}$.

Next, the interpolated ground height, $z_{int}$, at the current output range and the number of vertical output points, $i_{zg}$, that correspond to this ground height are determined. First, the interpolated ground height is given by

$$z_{int} = y_{last} + (y_{cur} - y_{last})xx$$

where the parameter $xx$ is given in terms of the PE range step $\Delta r_{PE}$ by

$$xx = \frac{r_{out} - r_{last}}{\Delta r_{PE}}.$$

Having determined $z_{int}$, $i_{zg}$ is then computed from

$$i_{zg} = \text{INT}\left(\frac{z_{int} - hm_{ref}}{\Delta z_{out}}\right).$$

where $\Delta z_{out}$ is the output height increment. Next, all elements in array $mpfl$ from 1 to $i_{zg}$ are set to zero, and the index $j_{start}$, representing beginning valid loss values in the $mpfl$ array, is set to the maximum of 0 or $i_{zg}$, plus $io$.

If the airborne model is required ($i_{hybrid}=0$), then the maximum tangent angle $\alpha_{ter}$ from the antenna height to the terrain height at the current range is determined from

$$\alpha_{ter} = \text{MAX} \left( \text{TAN}^{-1} \left( \frac{z_{int} - ant_{ref} - \frac{r_{out}^2}{\text{twoka}_{down}}}{r_{out}} \right) \alpha_{ter} \right),$$
where $\alpha_{\text{ter}}$ in the argument above is the maximum angle computed from previous references to the CALCLOS SU.

If the current output range is greater than the range $r_{\text{pest}}$ at which PE solutions are valid, then the calculation of loss values is begun. If this condition is not satisfied, then the $mpfl$ array is set to -1000 for values of the array index from $j_{\text{start}}$ up to and including the number of output height points desired ($n_{\text{zout}}$), $j_{\text{end}}$ is set equal to $j_{\text{start}}$ and the SU is exited.

Once it is determined that loss calculations will be performed, several parameters are computed. Both parameters $i_{p1}$ and $i_{p2}$ are first set to 0. If the logical variable $f_{\text{ier}}$ is ‘.true.’, then a terrain case is being performed. The two indices $i_{p1}$ and $i_{p2}$ are given by

\[
\begin{align*}
  i_{p1} &= \text{MAX} \left( 0, \text{INT} \left( \frac{y_{lb}}{\Delta_{\text{out}}} \right) \right) \\
  i_{p2} &= \text{MAX} \left( 0, \text{INT} \left( \frac{y_{ch}}{\Delta_{\text{out}}} \right) \right) .
\end{align*}
\]

These indices indicate the first output height point in array $zout$ where propagation loss will be computed at the last and current PE ranges. Next, the output heights $zout_{i_{p1}}$ and $zout_{i_{p2}}$, relative to $y_{\text{last}}$ and $y_{\text{cur}}$, respectively, are checked to make sure they are positive. If not, the two indices $i_{p1}$ and $i_{p2}$ are incremented by a value of 1. For values of the array index from 0 up to $i_{p1}$, the array of propagation factors $rfac1$ at valid height points for range $r_{\text{last}}$ are set to 0. For values of the array index from 0 up to $i_{p2}$, the array of propagation factors $rfac2$ at valid height points for range $r_{\text{out}}$ are also set 0.

If $j_{\text{start}}$ is less than both $i_{p1}$ and $i_{p2}$ then the variable $i_{zg}$ is recomputed as

\[
i_{zg} = \text{MAX} \left( i_{zg}, \text{MIN} \left( i_{p1}, i_{p2} \right) \right)
\]

and the $mpfl$ array at index $i_{zg}$ is set equal to $-999$. $j_{\text{start}}$ is then recomputed as the minimum of 0 and $i_{zg}$, plus $i_{o}$.

Next, the height/integer value, $j_{\text{end}}$, indicating the end of valid loss values, is determined as
\[ j_{end} = \max\left(0, \text{INT} \left( \frac{z_{lim} - h_{ref}}{\Delta z_{out}} \right) \right) \quad \text{if } PE \text{ flag is 'true', otherwise} \]
\[ j_{end} = \max\left(0, \text{NINT} \left( \min \left[\max \left( z_{lim}, h_{lim_{i_{\text{start}}}} \right) - h_{ref} \right], \frac{z_{lim} - h_{ref}}{\Delta z_{out}} \right) \right) \].

where \( i_{\text{start}} \) is the current output range step, and \( h_{lim_{i_{\text{start}}}} \) is the height at the current output range step separating the PE region from the FE, RO, or XO regions. Finally, \( j_{end} \) is given by the minimum of \( j_{end} \) (as computed above) and \( n_{out} \). If \( j_{end} \) is less than \( j_{\text{start}} \), then the \( mpfl \) array for elements \( j_{end}+1 \) to \( n_{out} \) is set equal to \(-1000\) and the SU is exited.

The propagation loss values are determined from the propagation factors \( r_{fac1_i} \) and \( r_{fac2_i} \) and from the parameter \( xx \) defined earlier in this section. If \( r_{\text{log}_{\text{list}}} \) \( (10 \text{ LOG}(r_{\text{last}})) \) is greater than zero (it is initialized to 0 for \( i_{\text{start}}=1 \)), then the GETPFAC SU is referenced to determine the propagation factor \( r_{fac1_i} \), which is given by

\[ r_{fac1_i} = \text{GETPFAC}\left(U_{\text{last}}, r_{\text{log}_{\text{list}}}, \Delta z_{PE}, z_{out_i} - y_{\text{last}} \right) \quad i = i_{p1}, i_{p1}+1, \ldots, j_{end} \]

where \( U_{\text{last}} \) is the complex field array at the previous PE range. Next, the propagation factor \( r_{fac2_i} \) is given by

\[ r_{fac2_i} = \text{GETPFAC}\left(U, r_{\text{log}}, \Delta z_{PE}, z_{out_i} - y_{\text{cur}} \right) \quad i = i_{p2}, i_{p2}+1, \ldots, j_{end} \]

where \( U \) is the complex field array at the current PE range, and \( r_{\text{log}} \) is \( 10 \text{ LOG}(r) \).

Next, if using the partial hybrid mode (PE & XO models), heights corresponding to areas outside the valid PE calculation region are determined and propagation loss is set equal to \(-1000\) within \( mpfl \) for those heights. If using the full or partial hybrid modes, the propagation factor at the last PE height point is determined at both the previous and current PE ranges. Linear interpolation is then performed to compute the propagation loss at range \( r_{out} \) and height \( z_{lim} \). The loss and height are then stored in array \( ffr_{out} \) for subsequent interpolation in the EXTO SU.

Next, the propagation factor and loss at range \( r_{out} \) is found by interpolating between the current and previous PE ranges. The propagation factor in dB, and the propagation loss at range \( r_{out} \) is given by

\[ F_{\text{db}} = r_{fac1_i} + (r_{fac2_i} - r_{fac1_i}) \times x \]
\[ r_{loss_i} = f_{sl_{i_{\text{start}}}} - F_{\text{db}} \quad ; \quad i = i_{\text{start}}, i_{\text{start}}+1, \ldots, j_{\text{end}} \]

where \( f_{sl_{i_{\text{start}}}} \) is the free-space loss in dB at range \( r_{out} \).
If the troposcatter calculation flag \( T_{tropo} \) is \( \text{‘true.’} \), then the TROPOSCAT SU is referenced to compute troposcatter loss from height \( z_{outj_{\text{start}}} \) to \( z_{outj_{\text{end}}} \) and this is added, if necessary, to \( r_{loss} \).

Finally, the gaseous absorption loss \( g_{\text{asloss}} \) is added to \( r_{loss} \) and the loss and propagation factor in centibels is given by

\[
mpfl_{1,i} = \text{NINT}(10 \times r_{loss_i}) \\
mpfl_{2,i} = \text{NINT}(10 \times (f_{\text{fsI}}_{\text{sup}} - r_{loss_i})); \quad i = j_{\text{start}}, j_{\text{start}} + 1, \ldots, j_{\text{end}}
\]

with the remaining elements in \( mpfl \) set equal to -1000 (i.e., \( mpfl_k = -1000 \) for \( k = j_{\text{end}} + 1 \) to \( n_{\text{out}} \)) before exiting.

Table 64 and Table 65 identify, describe the purpose for, state the units of, and show the computational source for each input and output data element, respectively, of the CALCLOSS SU.

5.2.3 DOSHIFT SU

The purpose of the DOSHIFT SU is to shift the field by the number of bins, or PE mesh heights corresponding to the local ground height.

Upon entry, the number of bins to be shifted is determined. First, the difference $y_{\text{diff}}$ between the height of the ground $y_{\text{last}}$ at the previous range and that at the current PE range $y_{\text{cur}}$ is determined from

$$y_{\text{diff}} = y_{\text{cur}} - y_{\text{last}}.$$  

The number of bins to be shifted, $k_{\text{bin}}$, is found from

$$k_{\text{bin}} = \text{NINT} \left( \frac{|y_{\text{diff}}|}{\Delta z_{\text{PE}}} \right).$$

The PE solution $U$ is then shifted downward if the local ground is currently at a positive slope ($y_{\text{diff}} > 0$), upward if the local ground is at a negative slope ($y_{\text{diff}} < 0$), and otherwise not shifted. When the PE solution has been shifted down, the value of the PE solution $U$ for the upper $k_{\text{bin}}$ elements are set to zero. Likewise, when the PE solution has been shifted upwards, the lower $k_{\text{bin}}$ elements are set to zero.

Table 66 and Table 67 identify, describe the purpose for, state the units of, and show the computational source for each input and output data element, respectively, of the DOSHIFT SU.

5.2.4 Discrete Sine/Cosine Fast-Fourier Transform (DRST) SU

A function with a common period, such as a solution to the wave equation, may be represented by a series consisting of sines and cosines. This representation is known as a Fourier series. An analytical transformation of the function, known as a Fourier transform, may be used to obtain a solution for the function.

The solution to the PE approximation to Maxwell's wave equation is obtained by using such a Fourier transformation function. The APM CSCI uses only the real-valued sine or cosine transformation in which the real and imaginary parts of the PE equation are transformed separately. Which transform is performed is dependent on the value of an integer flag provided by the calling SU. The Fourier transformation provided with the APM CSCI is described by Bergland (Ref. 1) and Cooley, Lewis, and Welsh (Ref. 2). The FORTRAN source code is listed in Appendix A.

Other sine/cosine fast-Fourier transform (FFT) routines are available in the commercial market, and such a sine/cosine FFT may already be available within another NITES-NC CSCI. The selection of which FFT ultimately used by the APM CSCI is left to the application designer as every sine/cosine FFT will have hardware and/or software performance impacts. For this reason, it is beyond the scope of this document to describe the numerical implementation of the FFT algorithm.

Table 68 and Table 69 identify, describe the purpose for, state the units of, and show the computational source for each input and output data element, respectively, of the DRST SU.

5.2.5 Flat-earth Model (FEM) SU

The purpose of the FEM SU is to compute propagation loss at a specified range based upon flat-earth approximations. The following steps 1 through 10, are performed for each APM height output point \( j \) from \( j_{fs} \) to \( j_{fe} \).

1. The receiver height at the \( j^{th} \) output point, \( z_{outj} \), is first adjusted relative to the antenna height for both the direct and reflected ray paths and is also corrected for earth curvature and average refraction. The receiver heights, \( z_m \) and \( z_p \), relative to both the real (direct) and image (reflected) antenna height, respectively, are defined as follows:

\[
z_m = z_{outma_j} - \frac{r_{out}^2}{2 \cdot twoka} \\
z_p = z_{outpa_j} - \frac{r_{out}^2}{2 \cdot twoka}
\]

where \( z_{outma_j} \) and \( z_{outpa_j} \) represent the output height \( z_{out} \) relative to the “real” and “image” antenna heights, respectively, with respect to mean sea level. \( twoka \) is twice the effective earth radius as calculated in the FILLHT SU.

2. Next, the point or range, of reflection, \( x_{reflect} \), is given by

\[
x_{reflect} = \frac{r_{out} \cdot \frac{ant_{ref}}{z_p}}{\frac{ant_{ref}}{z_p}}
\]
This quantity is used when referencing the GETREFCOEF SU.

3. The elevation angles for the direct- and reflected-path rays, $\alpha_d$ and $\alpha_r$, respectively, are given as

$$\alpha_d = \tan^{-1} \left( \frac{z_m}{r_{out}} \right)$$

$$\alpha_r = \tan^{-1} \left( \frac{z_p}{r_{out}} \right)$$

4. The ANTPAT SU is referenced with the direct-path elevation angle to obtain the antenna pattern factor for the direct-path ray, $f(\alpha_d)$; and with the grazing angle (opposite of the reflected-path ray angle) to obtain the antenna pattern factor for the surface-reflected ray, $f(-\alpha_r)$.

5. The path lengths for both the direct-path, $r_1$, and surface-reflected path, $r_2$, are computed from simple right triangle calculations, as

$$r_1 = \sqrt{z_m^2 + r_{out}^2}$$

$$r_2 = \sqrt{z_p^2 + r_{out}^2}$$

6. The GETREFCOEF SU is referenced with the reflected-path ray angle to obtain the amplitude, $R_{mag}$, and phase angle, $\varphi$, of the surface-reflection coefficient.

7. From the two path lengths, the surface-reflection phase lag angle, and the free-space wave number, $k_o$, the total phase angle is determined as

$$\Omega = (r_2 - r_1)k_o + \varphi$$

8. The square of the coherent sum of both the direct-path ray and surface-reflected path ray is computed as

$$f_{sum}^2 = \left| f(\alpha_d)^2 + R_{mag}^2 f(-\alpha_r)^2 + 2f(\alpha_d)R_{mag}f(-\alpha_r)\cos(\Omega) \right|$$

9. The propagation factor in decibels, $F_{dB}$, is computed as

$$F_{dB} = 10 \log_{10} \left[ \max \left( f_{sum}^2, 10^{-25} \right) \right]$$
A limit of -250 dB was put on $F_{dB}$ to avoid underflow problems.

10. Finally, the propagation factor and loss for the output point $z_{outj}$ is calculated and rounded to the nearest centibel as

$$mpfl_{1,j} = \text{NINT}\left(10(L_{fs} - F_{dB} + r_{gas\ att})\right)$$

$$mpfl_{2,j} = \text{NINT}\left(10(L_{fs} - mpfl_{1,j})\right)$$

where $L_{fs}$ is the free-space loss term in decibels and is given by

$$L_{fs} = 20 \log_{10}(r_{1}) + p_{l\ const}.$$  

Table 70 and Table 71 identify, describe the purpose for, state the units of, and show the computational source for each input and output data element, respectively, of the FEM SU.

5.2.6 Fast-Fourier Transform (FFT) SU

The purpose of the FFT SU is to separate the real and imaginary components of the complex PE field into two real arrays and then reference the DRST SU to transform each portion of the PE solution.

For a transform size, \( n_{fft} \), the real and imaginary parts of the complex PE field array \( U \), respectively, are found for the index \( i \) from 0 to \( n_{fft} \):

\[
xdum_{i} = \text{REAL}(U_{i}) \\
ydum_{i} = \text{IMAG}(U_{i})
\]

The DRST SU is referenced in turn for \( xdum \) and \( ydum \) along with \( ln_{fft} \), the power of the transform size to the base 2. The real and imaginary parts of the resulting transform arrays are then converted to the complex array \( U \) for \( i \) equal 0 to \( n_{fft} \) by

\[
U_{i} = \text{CMPLX}(xdum_{i},ydum_{i})
\]

Table 72 and Table 73 identify, describe the purpose for, state the units of, and show the computational source for each input and output data element, respectively, of the FFT SU.

5.2.7 Free-Space Range Step (FRSTP) SU

The purpose of the FRSTP SU is to propagate the complex PE solution in free space by one range step.

Upon entry the PE field, \( farray \), is transformed to p-space (Fourier space) and its array elements are multiplied by corresponding elements in the free-space propagator array, \( frsp \). Before exiting, the PE field is transformed back to z-space. Both transforms are performed by referencing the FFT SU.

5.2.8 FZLIM SU

The purpose of the FZLIM SU is to calculate and store the outward propagation angle and propagation factor at the top of the PE region for the current PE range. The following steps 1 through 5 are performed for each reference to the FZLIM SU.

1. The GETPFAC SU is referenced to determine the propagation factor $F_{dB}$ at height $z_{lim} - y_{cur}$.

2. If this is the first reference to the FZLIM SU ($iz = 1$), then the GETPFAC SU is referenced to determine the propagation factor, $F_{dB_{lst}}$, at the previous PE range. A linear interpolation is performed on $F_{dB}$ and $F_{dB_{lst}}$ to compute the propagation factor at range $r_{at}$ where the XO region begins. The interpolated propagation factor and the outward propagation angle, $F_{rat}$ and $a_{rat}$, respectively, are stored in array $ffacz$. Next, a reference to the SAVEPRO SU is made to store the refractivity profile at the current range from height $z_{lim}$ to the maximum desired output height.

3. A reference is made to the SPECEST SU to determine the outward propagation angle, $\vartheta_{out}$. The counter $iz$ is incremented, but is limited to $iz_{max}$. The propagation factor $F_{dB}$, current PE range $r$, and $\vartheta_{out}$ (with maximum limit of $a_{at}$) are stored in $ffacz_{1,iz}$, $ffacz_{2,iz}$, and $ffacz_{3,iz}$, respectively.

4. If $iz$ is greater than 2, then the propagation angle is checked and slightly altered to avoid extreme spiking when using these angles in the XO region. If $f_{ier}$ is ‘.false.’, then the angle stored in $ffacz$ is the smaller of $\vartheta_{out}$ or the previously stored angle.
Now, if \( f_{\text{ter}} \) is ‘.false.’, or conversely, if \( f_{\text{ter}} \) is ‘.true.’ AND \( iz \) is less than or equal to 10, then the \( iz \)th angle stored is adjusted and given by

\[
\alpha_{\text{diff}} = ffacz_{3,iz} - ffacz_{3,iz-1} \\
ffacz_{3,iz} = ffacz_{3,iz-1} \pm \text{MIN}\left(\alpha_{\text{diff}}, 10^{-4}\right)
\]

where ‘+’ or ‘-’ is used depending on the sign of \( \alpha_{\text{diff}} \).

5. Before exiting, a final reference to the SAVEPRO SU is made to store the refractivity profile from height \( z_{\text{lim}} \) to the maximum desired output height at the current range.

Table 76 and Table 77 identify, describe the purpose for, state the units of, and show the computational source for each input and output data element, respectively, of the FZLIM SU.

5.2.9 Get Propagation Factor (GETPFAC) SU

The purpose of the GETPFAC SU is to determine the propagation factor at a specified height.

First, linear interpolation is performed on the magnitudes of the PE field at bins $k$ and $k+1$ to determine the magnitude $p_{mag}$ of the field at the receiver height, $z_r$:

$$ p_{mag} = |U_k| + f_r \left( |U_{k+1}| - |U_k| \right) $$

where the interpolation fraction $f_r$ is determined from

$$ f_r = \frac{z_r - k \Delta z_{PE}}{\Delta z_{PE}}; \quad k \Delta z_{PE} \leq z_r < (k+1) \Delta z_{PE} $$

$$ k = \text{INT} \left( \frac{z_r}{\Delta z_{PE}} \right). $$

$p_{mag}$ is constrained to be not less than $10^{-12} \mu V/m$. Finally, the propagation factor in dB, $F_{dB}$ is given by

$$ F_{dB} = 20 \log_{10} (\max(p_{mag}, 10^{-12})) + r_{log}. $$

Table 78 and Table 79 identify, describe the purpose for, state the units of, and show the computational source for each input and output data element, respectively, of the GETPFAC SU.

5.2.10 Get Reflection Coefficient (GETREFCOEFF) SU

The purpose of the GETREFCOEFF SU is to compute the Fresnel complex reflection coefficient for a given grazing angle, ψ.

Upon entering, the proper dielectric constant $n_{c_{i}}^2$ to be applied to the reflected ray must be determined. A DO WHILE loop is performed on array $rgrnd$ to determine the index $i$ at which the range $x_{reflect}$ (range at which ray is reflected) falls between two consecutive range points in $rgrnd$. Once this is found, the corresponding dielectric constant $n_{c_{i}}^2$ is used in the following equations to compute the reflection coefficient:

$$
\begin{align*}
\Gamma_V &= \frac{n_{c_{i}}^2 \sin(\psi) - \sqrt{n_{c_{i}}^2 - \cos^2(\psi)}}{n_{c_{i}}^2 \sin(\psi) + \sqrt{n_{c_{i}}^2 - \cos^2(\psi)}}, \\
\Gamma_H &= \frac{\sin(\psi) - \sqrt{n_{c_{i}}^2 - \cos^2(\psi)}}{\sin(\psi) + \sqrt{n_{c_{i}}^2 - \cos^2(\psi)}}
\end{align*}
$$

where $\Gamma_V$ and $\Gamma_H$ represent the reflection coefficients for vertical and horizontal polarization, respectively, and $n_{c_{i}}^2$ is computed in the DIEINIT SU and is given by

$$
n_{c_{i}}^2 = \varepsilon_i + j60\sigma_i\lambda.
$$

$\varepsilon_i$ and $\sigma_i$ are the relative permittivity and conductivity, respectively, to be applied at range $rgrnd_i$, and $\lambda$ is the wavelength.
If rough surface calculations are required \((ruf = \text{true}.)\) the Miller-Brown roughness reduction factor is computed. Wind speeds specified by the calling CSCI are allowed to vary with range; therefore, an interpolation is performed to obtain the wind speed \(\omega_s\) at the current range. The sea surface rms wave height is then computed from

\[
ruf_{\text{rt}} = ruf_{\text{fac}} \omega_s^2, \]

and the roughness reduction factor \(\rho\) is determined by

\[
\rho = \left(3.2x_g^2 - 2 + \sqrt{(3.2x_g^2 - 7x_g + 9)}\right)^{-\frac{1}{2}}
\]

where

\[
x_g = \frac{1}{2} [ruf_{\text{rt}} \text{ SIN} (\psi)]^2.
\]

Table 80 and Table 81 identify, describe the purpose for, state the units of, and show the computational source for each input and output data element, respectively, of the GETREFCOEF SU.

5.2.11 Mixed Fourier Transform (MIXEDFT) SU

The purpose of the MIXEDFT SU is to propagate the PE field in free space one PE range step, applying the Leontovich boundary condition, using the mixed Fourier transform as outlined by Kuttler and Dockery (Ref.8). For finite conducting boundaries (i.e., if vertical polarization is specified or rough surface calculations are required) and the frequency is less than 400 MHz, the central difference form of the DMFT is used. If the frequency is greater than 400 MHz, the backward difference form of the DMFT is used.

Upon entering the SU, the first and last elements of the $w$ array $w_0$ and $w_{n_{fft}}$ are initialized to 0. If using the central difference form of the DMFT ($i_{alg} = 1$), the following steps 1 through 6 are performed.

1. The difference field for the vertical PE calculation grid is computed from the PE field as

$$w_i = \frac{U_{i+1} - U_{i-1}}{2\Delta x_{PE}} + \alpha_{h,v} U_i; \quad i = 1, 2, 3, \ldots, n_{m1}$$

2. Next, the FRSTP SU is referenced to transform $w$ to p-space, propagate the field forward one PE range step, and is transformed back to z-space upon return.
3. The coefficients used in the central difference form of the mixed transform, $c_{k1}$ and $c_{k2}$, are propagated to the new range as follows:

$$c_{k1} = c_{k1} \ C_{1x}$$
$$c_{k2} = c_{k2} \ C_{2x}$$

4. The particular solution $y_m$ of Kuttler’s difference equation is then computed as follows:

$$y_m_i = 2 \Delta z_{PE} \ w_i + R_T \ w_{i-1} ; \quad i = 1, 2, 3, ..., n_{m1}$$
$$y_m_0 = 0,$$

where $R_T$ is a quadratic root as computed in the GETALN SU.

5. The complex PE field $U$ is then determined from

$$U_{n-i} = R_T \ (y_m_{n-i} - U_{n-1+i}); \quad i = 1, 2, 3, ..., n_{ffi}$$
$$U_0 = 0$$

6. The final step in computing the PE field $U$ is

$$U_i = U_i + a_r \ r_{n_i} + b_r \ r_{n-i} (-1)^{n-i}; \quad i = 0, 1, 2, ..., n_{ffi},$$

where

$$a_r = c_{k1} - R_k \left( \sqrt[2]{} U_0 + \sqrt[2]{} U_{n_{ffi}} r_{n_{ffi}} + \sum_{i=1}^{n_{ffi}-1} U_{r n_i} \right),$$
$$b_r = c_{k2} - R_k \left( \sqrt[2]{} U_0 r_{n_{ffi}} + \sqrt[2]{} U_{n_{ffi}} + \sum_{i=1}^{n_{ffi}-1} U_{n-i} r_{n_i} (-1)^{i} \right).$$

If using the backward difference form of the DMFT ($i_{alg} = 2$), then the following steps 1 through 6 are performed.

1. The difference field for the vertical PE calculation grid is computed from the PE field as

$$w_i = U_i - R_T U_{i-1} ; \quad i = 1, 2, 3, ..., n_{m1}$$
2. Next, the FRSTP SU is referenced to transform \( w \) to p-space, propagate the field forward one PE range step, and is transformed back to z-space upon return.

3. The coefficient \( cmft \) is then propagated forward one range step via

\[
cmft = cmft \times cmft_x.
\]

4. The particular solution of the field \( U \) is now computed from

\[
U_i = w_i + R_i U_{i-1}; \quad i = 1, 2, 3, ..., n_{ft} \\
U_0 = 0.
\]

5. The coefficient \( a_r \) for the homogeneous solution is determined as

\[
a_r = cmft - \sum_{i=0}^{n_{ft}-1} U_i r_{ni}.
\]

6. Finally, the PE field \( U \) for the backward difference DMFT is computed as the sum of the homogeneous and particular solutions:

\[
U_i = U_i + a_r r_{ni}; \quad i = 0, 1, 2, ..., n_{ft}.
\]

Table 82 and Table 83 identify, describe the purpose for, state the units of, and show the computational source for each input and output data element, respectively, of the MIXEDFT SU.

5.2.12 Parabolic Equation Step (PESTEP) SU

The purpose of the PESTEP SU is to compute propagation loss at a specified range based upon the split-step Fourier PE algorithm.

Upon entering the PESTEP SU, if the current output range step, \(i_{esp}\), is equal to 1, the current PE range \(r\) and \(r_{log}\) (10 times the logarithm of \(r\)) are set equal to zero. The current PE range step \(i_{PEsp}\) is also set equal to 0. An iterative DO WHILE loop is then begun to advance the PE solution such that for the current PE range, a PE solution is calculated from the solution at the previous PE range. This iterative procedure is repeated in the DO WHILE loop until \(r\) is greater than the output range \(r_{out}\). The following steps (1 through 8) are performed for each PE range step within the DO WHILE loop.

1. First, if the current PE range, \(r\), is greater than zero, then the height of the ground at the previous PE range \(y_{last}\) is set to the height of the ground at the current PE range \(y_{cur}\). Next, the previous PE range \(r_{last}\) is set equal to the current PE range \(r\). The
complex PE field, $U$, of the previous range is stored in array $U_{last}$ for subsequent horizontal interpolation at range $r_{out}$. In addition, $r$ is incremented by one PE range step, $\Delta r_{PE}$. A new $r_{log}$ is computed and the PE range step $i_{PE_{esp}}$ is incremented by one. Finally, the range at which interpolation for range-dependent refractivity profiles is performed, $r_{mid}$, is also incremented by one-half the PE range step.

2. If performing a terrain case ($f_{terr}$ is ‘.true.’), the ground heights, $y_{cur}$ and $y_{cur\text{m}}$, at range $r$ and $r_{mid}$, respectively, must be determined. $y_{cur}$ is set equal to the terrain height at the current PE range step, $ty_{h_{PE_{esp}}}$. $y_{cur\text{m}}$ is determined as

$$y_{cur\text{m}} = \frac{1}{2}(ty_{h_{PE_{esp}}} + y_{cur}).$$

If $y_{cur}$ is less than $y_{last}$, then the DOSHIFT SU is referenced to shift the field accordingly.

3. If the APM CSCI is being used in a range-dependent mode (i.e., the number of profiles $n_{prof}$ is greater than 1), or if a terrain profile is specified, the REFINTER SU is referenced to compute a new modified refractive index profile, $\text{profint}$, adjusted by the local ground height $y_{cur\text{m}}$ at range $r_{mid}$. A new environmental phase array, $\text{envpr}$, is re-computed based on this new refractivity profile.

4. The current PE range is then checked against the range of the current ground type given by array $r_{grnd}$, and, if necessary, the ground type counter $i_{g}$ is incremented. The GETALN SU is then referenced to compute a new surface impedance $\alpha_{h,\nu}$ if vertical polarization is required or if performing rough surface calculations.

5. In order to propagate the field in free space one PE range step, the MIXEDFT SU is referenced if the DMFT algorithm is required; otherwise, the FRSTP SU is referenced. The field is then multiplied by the environmental array $\text{envpr}$.

6. Next, if the current terrain slope is positive, the DOSHIFT SU is referenced to shift the field by the appropriate number of bins.

7. If XO calculations are to be performed ($i_{xo} \geq 1$) and the current PE range is greater than $r_{atz}$, then the FZLIM SU is referenced to determine and store the outward propagation angle at the top of the PE region for subsequent use in the EXTO SU.

8. Finally, after the output range $r_{out}$ is reached and the DO WHILE loop exited, the CALCLOS SU is referenced to obtain the propagation loss values at the desired output heights at the current output range $r_{out}$. 

136
Table 84 and Table 85 identify, describe the purpose for, state the units of, and show the computational source for each input and output data element, respectively, of the PESTEP SU.

5.2.13 Ray Trace (RAYTRACE) SU

Using standard ray trace techniques, a ray is traced from a starting height $ant_{\text{ref}}$ and range 0, with a specified starting elevation angle, $\alpha$, to a termination range, $x_r$. As the ray is being traced, an optical path length difference $pl_d$ (the difference between the actual path length and $x_r$) and a derivative of range with respect to elevation angle, $dx d\alpha$, are being continuously computed. If the ray should reflect from the surface, a grazing angle, $\psi$, is determined. Upon reaching the termination range, a terminal elevation angle, $\beta$, is determined along with a termination height, $z_r$.
The raytrace is conducted by stepping in profile levels and computing ending values. A number of stepping scenarios, based upon starting and ending elevation angles, determine the program flow of the RAYTRACE SU. These scenarios are a ray that is upgoing, a ray that is downgoing, and a ray that turns around within a layer.

Upon entering the SU, a running range, \(x_{sum}\), the range at which a ray is reflected, \(x_{reflect}\), \(dx d\alpha\), \(p l_d\), \(\psi\), and a ray type (direct or reflected) flag, \(i_{type}\), are initialized to zero. A temporary beginning elevation angle, \(a_{start}\), is set equal to \(\alpha\), and an environmental profile level counter, \(i\), is set equal to the array index for the height in the RO region corresponding to the transmitter height, \(i_{start}\).

The sub-steps within the following steps (1 and 2) are now repeated while \(x_{sum}\) remains less than the termination range \(x_r\). Upon failure to meet this repetition criterion, the SU program flow continues with step 3 below.

1. The beginning angle \(a_{start}\) is examined to determine if the ray is initially upgoing (i.e., \(a_{start} \geq 0\)) or downgoing. If it is upgoing, the SU program flow continues with steps 1.a through 1.e; otherwise the program flow continues with step 2 below.

   a. The level counter is examined and if the ray is in the highest layer, (i.e., \(i = i_{levels}\)), the ending angle, height, range/angle derivative and path length difference are given as

\[
\beta = a_{start} + (x_r - x_{sum})gr_i,
\]

\[
z_r = z_{rt} + \frac{\beta^2 - a_{start}^2}{2 gr_i},
\]

\[
dx d\alpha = dx d\alpha + \frac{1}{gr_i}\left(\frac{\alpha}{\beta} - \frac{\alpha}{a_{start}}\right),
\]

\[
pl_d = pl_d + \frac{1}{gr_i}\left[(rm_i - a_{start}^2)\left(\beta - a_{start}\right) + \frac{1}{3}\left(\beta^3 - a_{start}^3\right)\right],
\]

respectively, where \(gr\) is an intermediate M-unit gradient, \(rm\) is an intermediate M-unit, and \(z_{rt}\) is an intermediate height. Satisfaction of this condition causes the failure of the repetition criterion, and the SU program flow continues with step 3 below.
b. If the ray is not in the highest layer, the ray must be examined to determine if it will turn around and become a downgoing ray within the current layer. This is done by looking at the radical term, \( rad \), which will be used in the ending angle calculation. The radical term is given as

\[
rad = a_{start}^2 + q_i 
\]

where \( q \) is an intermediate M-unit difference. If \( rad \) is greater than or equal to zero, a solution for the ending angle is possible. The ray will not turn around and the program flow continues with step 1.c, otherwise the program flow continues with step 1.d.

c. Before calculations can continue, the possible ending range must be compared to the termination range. This possible ending range is determined as

\[
x_{temp} = x_{sum} + \frac{\beta - a_{start}}{gr_i},
\]

\[
\beta = \sqrt{rad}.
\]

This possible ending range is compared to the termination range, and, if it is larger, the ending angle, height, range/angle derivative, and path length difference are computed from equations given in step 1.a. Satisfaction of this condition causes the failure of the repetition criterion, and the SU program flow continues with step 3 below.

If the ray has not reached the termination range, \( x_{sum} \) is updated to \( x_{temp} \); the range/angle derivative and path length difference are computed from equations given in step 1.a, where \( \beta = \sqrt{rad} \); \( a_{start} \) is updated to \( \beta \); the level counter is incremented by one; and the program flow returns to step 1 above.

d. If the ray has, in fact, turned around within the current layer, a determination must be made for the ray reaching a full range step within the still upgoing segment, for the ray reaching a full range step within the downgoing segment, or the ray exceeding the termination range. The full range step is given by

\[
x_{temp} = x_{sum} - \frac{a_{start}}{gr_i},
\]

which is compared to the termination range. If it exceeds the termination range, the ending angle, the ending height, the range/angle derivative, and the path
length difference are determined from equations given in step 1.a. Satisfaction of this condition causes the failure of the repetition criterion, and the SU program flow continues with step 3 below. If the termination range has not been exceeded, further examination of the ray’s segments must be made.

e. At this point, \( x_{sum} \) is updated to \( x_{temp} \); \( x_{temp} \) is recalculated as shown in step 1.d; and \( x_{temp} \) is again compared to the termination range. If the termination range has been exceeded, the ending angle is given as

\[
\beta = (x_r - x_{sum})gr_i,
\]

and the ending height, the range/angle derivative, and the path length difference are now determined from equations shown in step 1.a. Satisfaction of this condition causes the failure of the repetition criterion, and the SU program flow continues with step 3 below.

If the termination range has not been exceeded, \( x_{sum} \) is updated to \( x_{temp} \); \( \beta \) is updated to \(-\alpha_{start}\); the range/angle derivative and path length difference are determined from equations shown in step 1.a; \( \alpha_{start} \) is updated to \( \beta \); and the program flow returns to step 1 above.

2. **Note!** The equations for the upgoing ray within step 1 above apply equally to the downgoing ray except where specified otherwise. However, in applying these equations to step 2, the level counter, \( i \), within the intermediate M-unit gradient sub-term, \( gr \), must be reduced by one.

The beginning angle \( \alpha_{start} \) has been examined in step 1 above and the ray has been determined to be initially downgoing. Similar to step 1 above, the ray must be examined to determine if it has turned around and has become an upgoing ray within the current layer. This is done by looking at the radical term, \( rad \), which will be used in the ending angle calculation. This radical term is given as

\[
rad = a_{start}^2 - q_{i-1}.
\]

If \( rad \) is greater than or equal to zero, a solution for the ending angle is possible. The ray has not turned around and the program flow continues with steps 2.a through 2.c below, otherwise the program flow continues with step 2.d.

a. Before calculations can continue, the possible ending range must be compared to the termination range. This possible ending range is determined from the equation given for \( x_{temp} \) in step 1.c, where \( \beta \) is now \(-\sqrt{rad}\). This possible ending range is compared to the termination range and if it is larger, the ending angle, the
ending height, the range/angle derivative, and the path length difference are computed from equations shown in step 1.a. Satisfaction of this condition causes the failure of the repetition criterion, and the SU program flow continues with step 3 below.

b. If the termination range has not been exceeded, $x_{sum}$ is updated to $x_{temp}$; the range/angle derivative and path length difference are computed as shown in step 1.a, where $\beta = -\sqrt{\text{rad}}$; $a_{start}$ is updated to $\beta$; and the level counter is decremented by one.

c. The level counter is examined and if it is zero, the ray has reflected from the surface. In this case, the ray type flag is set to 1 to indicate a reflection, the grazing angle is set as $\psi = |a_{start}|$, and $x_{reflect}$ is set equal to $x_{temp}$. At this point, a symmetry check is made. The idea of symmetry says that the ray will return to its starting height, at twice the reflection range, with an ending elevation angle opposite the starting elevation angle. Symmetry is used for APM speed efficiency so as to preclude redundant ray trace calculations on the upward path back to the starting height. Prior to applying symmetry, however, the possible ending range (twice $x_{sum}$) must be compared to the termination range. If the termination range is exceeded by making the symmetry assumption, $a_{start}$ is updated to $-a_{start}$ and the assumption is vacated. If not, however, the assumption is invoked and $a_{start}$ is updated to $-\alpha$; $x_{sum}$, $dx/a$, and $pl_d$, are doubled; and the level counter is restored to $i_{start}$. Control is now returned to the top of step 1 above.

d. From step 2, the ray has turned around within the current layer and is now an upgoing ray. Similar to the upgoing case of step 1, a determination must be made for the ray reaching a full range step within the still downgoing segment, for the ray reaching a full range step within the upgoing segment, or the ray exceeding the termination range. The full range step is given by $x_{temp}$ as computed step 1.d.

If the full range step exceeds the termination range, the ending angle, the ending height, the range/angle derivative, and the path length difference are computed from equations shown in step 1.a. Satisfaction of this condition causes the failure of the repetition criterion, and the SU program flow continues with section 3 below. If the termination range has not been exceeded, further examination of the ray’s segments must be made.

e. At this point, $x_{sum}$ is updated to $x_{temp}$; $x_{temp}$ is recalculated as in step 1.d, and $x_{temp}$ is again compared to the termination range. If the termination range has been exceeded, the ending angle is determined as in step 1.e; the ending height, range/angle derivative, and path length difference are determined as in step 1.a. Satisfaction of this condition causes the failure of the repetition criterion, and the SU program flow continues with step 3 below.
If the termination range has not been exceeded, \( x_{sum} \) is updated to \( x_{temp} \); \( \beta \) is updated to \(-a_{start}\); the range/angle derivative and path length difference are determined as in step 1.a; \( a_{start} \) is updated to \( \beta \), and the program flow returns to step 1 above.

3. Within APM, the terminal elevation angle is not allowed to be equal to zero. Therefore, if its absolute value is less than \( 10^{-10} \), it is reset to \( 10^{-10} \) while retaining its present sign.

Table 86 and Table 87 identify, describe the purpose for, state the units of, and show the computational source for each input and output data element, respectively, of the RAYTRACE SU.

5.2.14 Refractivity Interpolation (REFINTER) SU

The purpose of the REFINTER SU is to interpolate both horizontally and vertically on the modified refractivity profiles. Profiles are then adjusted so they are relative to the local ground height.

Upon entry, the number of height/refractivity levels, $lvlep$, for the current profile is set equal to the user-specified number of levels for all profiles specified, $lvlp$. For the range-dependent case, all profiles have the same number of levels.

If there is a range-dependent environment (i.e., $n_{prof} > 1$), horizontal interpolation to range $r_{ange}$ is performed between the two neighboring profiles that are specified relative to mean sea level. In this case, the following calculations are made. If $r_{ange}$ is greater than the range for the next refractivity profile $rv_2$, then the index $j$ (indicating the range of the previous refractivity profile) is set equal to the counter for the range of the current profile $i_s$; $i_s$ is then incremented by one. Next, the range of the previous refractivity profile $rv_1$ is set equal to $rv_2$, and $rv_2$ is set equal to the range of the $i_s^{th}$ profile, $rngprof_{is}$. The fractional range $fv$ for the interpolation is given by

$$fv = \frac{r_{ange} - rv_1}{rv_2 - rv_1}.$$

The array $refdum$, containing M-unit values for the current (interpolated) profile and the array $htdum$ containing height values for the current (interpolated) profile are determined from

$$refdum_i = refmsl_{i,j} + fv(refmsl_{i,s} - refmsl_{i,j}); \quad i = 1, 2, 3, \ldots lvlep$$

$$htdum_i = hmsl_{i,j} + fv(hmsl_{i,s} - hmsl_{i,j}); \quad i = 1, 2, 3, \ldots lvlep$$

where $refmsl$ and $hmsl$ are 2-dimensional arrays containing refractivity and height, respectively, with respect to mean sea level of each user-specified profile.

The REMDUP SU is referenced to remove duplicate refractivity levels, with $lvlep$ being the number of points in the profile at range $r_{ange}$. The PROFREF SU is then referenced to adjust the new profile (i.e., $refdum$ and $htdum$) relative to the internal reference height $h_{inter}$, corresponding to the minimum height of the terrain profile. The PROFREF SU is then referenced once more to adjust the profile relative to the local ground height $y_{curm}$, and upon exit from the PROFREF SU, the INTPROF SU is referenced to interpolate vertically on the refractivity profile at each PE mesh height point. This results in the $n_{fft}$-point profile array $profint$ containing the interpolated M-unit values for the refractivity at $r_{ange}$, where $n_{fft}$ is the transform size.

Upon exiting the REFINTER SU, $rv_1$ and index $j$ are saved for use upon the next reference of the SU.
Table 88 and Table 89 identify, describe the purpose for, state the units of, and show the computational source for each input and output data element, respectively, of the REFINTER SU.

5.2.15 Ray Optics Calculation (ROCALC) SU

The purpose of the ROCALC SU is to compute the RO components which will be needed (by the ROLOSS SU) in the calculation of propagation loss at a specified range and height within the RO region. These components are the magnitudes for a direct-path and surface-reflected ray, \( F_d^2 \) and \( F_r^2 \), respectively, and the total phase lag angle, \( \Omega \), between the direct-path and surface-reflected rays.

The RO region may be visualized as having a grid of points superimposed upon it. The grid points are defined at the intersection of a series of lines sloping upward from the origin and a series of vertical lines at varying ranges. The grid point counter \( k \) and the vertical lines are defined at varying ranges, two of which are represented by the terms \( x_{ROP} \), a range for which the RO calculations were previously performed, and \( x_{RON} \), the next calculation range.

The sloping line with the greatest angle (indicated by \( k = k_{\text{max}} \)) is a function of the maximum APM output height, \( h_{\text{ydif}} \), adjusted for terrain and reference heights, and the next calculation range. The sloping line with the least angle (indicated by \( k = k_{\text{minp}} \)) is a function of the height at the top of the PE region and the range of the previous RO calculations.

The following steps 1 through 4 are performed while the current range, \( x \), is greater than \( x_{RON} \).

1. The terms of Table 90 (defined in Table 91) are initialized or updated based upon the RO calculation range counter \( i_{ROP} \). If \( i_{ROP} \) equals -1, the terms are initialized; otherwise, the terms are updated. It should be noted that the terms must be computed in the order they appear in the table to ensure proper values are assigned to component terms.

</tbody>
</table>

2. To calculate the RO components at each vertical point for the next range, $x_{RON}$, a ray trace within a Newton iteration method is used to find a direct-path ray and a surface-reflected ray which will both originate at the transmitter height, $ant_{ref}$, and terminate at the same grid point, $z_k$. The results of the iteration are examined and if either of the rays has not been found, an adjustment in the lower boundary of the RO region is made. Following the conclusion of the iterations, the antenna pattern factors for each ray are obtained, a surface reflection coefficient for the surface-reflected ray is computed, and the RO components are calculated.

Prior to all calculations for each vertical point, the ray trace must be initialized with beginning direct-path and surface-reflected ray elevation angles, $\alpha_d$ and $\alpha_r$, respectively; and derivatives of height with respect to these elevation angles, $dxd\alpha_d$ and $dxd\alpha_r$. A starting assumption is made that the direct-path ray and the surface-reflected rays are parallel to each other. Thus, $\alpha_d$ is initialized as 0.001 $k_{max}$ and $\alpha_r$ is initialized as $-\alpha_d$. The RAYTRACE SU is referenced separately with $\alpha_d$ and $\alpha_r$ to obtain termination elevation angles, $\beta_d$ and $\beta_r$, and the two derivatives of range with respect to elevation angle, $dxd\alpha_d$ and $dxd\alpha_r$, which are used in turn to compute the needed derivatives of height with respect to elevation angle given as $-\beta_d dx d\alpha_d$ and $-\beta_r dx d\alpha_r$.

3. Once the raytrace has been initialized, the following steps 3.a through 3.f are performed for each vertical grid point, $z_k$, beginning with $k = k_{max}$ and subsequently decrementing $k$ downward while $k$ remains $\geq k_{minn}$. Once $k$ has reached zero, processing continues with step 4 below.

a. The termination height is computed as
\[ z_k = x_{RON} \times 0.001 \times k \]

where \( k \) is the grid point counter.

b. The Newton iteration method to find the direct path ray from \( \text{ant}_{\text{ref}} \) to \( z_k \) is started. This iteration is continued until the difference between the ray trace ending height \( z_d \) and \( z_k \) is less than a height difference tolerance \( z_{tol} \); but in any case, no more than 10 times. The direct-path elevation angle is given as

\[ \alpha_d = \alpha_d - \frac{z_d - z_k}{dzd\alpha_d} \]

where \( z_d \) and \( dzd\alpha_d \) are obtained from the ray trace initialization of step 2 above for the first iteration and from the previous iteration for subsequent iterations.

The RAYTRACE SU is referenced and a new \( dzd\alpha_d \) is calculated as \(-\beta_d \times dx \alpha_d\). This new \( dzd\alpha_d \) is examined and if it is less than \( 10^{-6} \), or if the ray type flag \( i_{\text{type}} \), returned from the RAYTRACE SU, indicates the ray has reflected, the lower boundary of the RO region is adjusted by setting \( k_{\text{minn}} \) equal to one more than \( k \), and the iteration for the direct ray is stopped.

c. The Newton iteration method to find the surface-reflected ray from \( \text{ant}_{\text{ref}} \) to \( z_k \) is now started. This iteration should be continued until the difference between the ray trace ending height, \( z_r \) and \( z_k \) is less than a height difference tolerance \( z_{tol} \); but in any case, no more than 10 times. The reflected-path elevation angle is given as

\[ \alpha_r = \alpha_r - \frac{z_r - z_k}{dzd\alpha_r} \]

where \( z_r \) and \( dzd\alpha_r \) are obtained from the ray trace initialization of step 2 above for the first iteration and from the previous iteration for subsequent iterations.

The RAYTRACE SU is referenced and a new \( dzd\alpha_r \) is calculated as \(-\beta_r \times dx \alpha_r\). This new \( dzd\alpha_r \) is examined and if it is less than \( 10^{-6} \), or if \( i_{\text{type}} \) indicates the ray is a direct ray, the lower boundary of the RO region is adjusted by setting \( k_{\text{minn}} \) equal to one more than \( k \), and the iteration for the surface-reflected ray is stopped.

d. A test is made to determine if the grazing angle, \( \psi \), (returned from the RAYTRACE SU) is less than the limiting value, \( \psi_{lim} \), and if so, the lower boundary of the RO region is adjusted by setting \( k_{\text{minn}} \) equal to \( k \).
e. The magnitudes for the direct-path and surface-reflected ray, $Fd^2$ and $Fr^2$ respectively, are now given as

$$Fd^2 = \left| \frac{x_{RO}}{d\alpha_d} \right| f^2(\alpha_d),$$

$$Fr^2 = \left| \frac{x_{RO}}{d\alpha_r} \right| [f(\alpha_r)R_{mag}]^2,$$

where the amplitude of the surface reflection coefficient, $R_{mag}$, is obtained from a reference to the GETREFCOEF SU; the antenna pattern factors $f(\alpha_d)$ and $f(\alpha_r)$ are obtained from references to the ANTPAT SU; and the derivatives of height with respect to elevation angle are obtained from the RAYTRACE SU within the Newton iteration of steps 3.b and 3.c above.

f. The total phase lag between the direct-path and surface-reflected rays is computed as

$$\Omega = (pl_r - pl_d)k_o + \varphi,$$

where the ray path lengths $pl_d$ and $pl_r$ are obtained from the RAYTRACE SU within the Newton iteration of steps 3.b and 3.c above; the reflection coefficient phase lag angle, $\varphi$, is obtained from a reference to the GETREFCOEF SU; and $k_o$ is the free-space wave number.

4. If the point counter $k$ has been reduced to zero by the procedures of steps 3.a through 3.f above, the surface values of magnitudes for the direct-path and surface-reflected rays are both set equal to the last value of $Fd^2$ and the total phase lag between the direct-path and surface-reflected rays is set equal to $\pi$. If vertical polarization has been specified, then a further calculation is performed for the special case when the RO output height is less than 0 due to the height adjustment of $y_{ref}$. A FE calculation is made at this lowest height and replaces the previous values of magnitudes for the direct and surface-reflected paths, along with a new phase lag.

Table 91 and Table 92 identify, describe the purpose for, state the units of, and show the computational source for each input and output data element, respectively, of the ROCALC SU.

### 5.2.16 Ray Optics Loss (ROLOSS) SU

The purpose of the ROLOSS SU is to calculate propagation factor and loss values at all valid RO heights at a specified range based upon the components of magnitude for a direct-path and surface-reflected ray, \( F_d \) and \( F_r \) respectively, and the total phase lag angle, \( \Omega \), between the two rays as determined by the ROCALC SU.

Upon entering the SU, the ROCALC SU is referenced to obtain the current values of the direct and reflected ray magnitudes, along with the phase lag for all heights at the specified range \( r_{out} \).

For purposes of computational efficiency, an interpolation from the magnitude and total phase lag angle arrays established by the ROCALC SU is made to obtain these three quantities at each APM vertical output mesh point within the RO region.

From the interpolated phase lag angle and ray magnitudes, a propagation factor is calculated which is used in turn with the free-space propagation loss, to obtain a propagation loss at each vertical APM output point.

A range ratio term to be used within the interpolation scheme is defined as

\[
\text{ratio} = \frac{r_{out} - x_{ROp}}{\Delta x_{RO}}.
\]

The phase lag angle and ray magnitude arrays have been filled at grid points defined by a series of sloping lines and the next and previous RO calculation range, \( x_{ROn} \) and \( x_{ROp} \), respectively. Which values to interpolate from are determined by the sloping line immediately above and the sloping line immediately below the current APM output point of interest. To begin the calculations, \( k_{lo} \) is initialized to \( k_{max} \), the line with the greatest angle.

The following steps 1 through 4 are now taken, decrementing downward in APM output points from the maximum output height index in the RO region, \( j_{max} \), to the

<table>

</tbody>
</table>
minimum output height index, in the RO region, $j_{\text{min}}$ where the index $j$ varies from $j_{\text{max}}$ to $j_{\text{min}}$.

1. Interpolation of $F_d^2$, $F_r^2$, and $\Omega$ values occurs in two stages. The first stage is horizontally, above and below the APM output point (i.e., along the lines $k_{lo}$ and $k_{hi}$). These values will be used in turn, in a vertical interpolation stage to obtain values at the APM output point itself. It may be, however, that more than one APM output point will fall between two adjacent $k$ lines. In this case, it would be redundant to perform the horizontal interpolation more than once. For this reason, a temporary $k$ line counter is established which will be used in comparison with $k_{lo}$ to determine if interpolation is necessary or if the previously interpolated horizontal values may again be used in the vertical interpolation. This temporary $k$ counter is given by

$$k_{\text{temp}} = \text{INT} \left( \frac{1000 zro_j}{r_{\text{out}}} \right)$$

where $j$ is the APM output point counter, and $zro_j$ is the $j^{th}$ output height point. If $k_{\text{temp}}$ is less than the current $k_{lo}$, the APM output point occurs below the current lower $k$ line and horizontal interpolations must be performed using the following steps 1.a through 1.c; otherwise, the horizontal interpolations are unnecessary and the SU may proceed with step 2.

a. The lower $k$ line, $k_{lo}$, is reset to $k_{\text{temp}}$ and the upper $k$ line, $k_{hi}$, is set to one more than $k_{lo}$.

b. In preparation for the interpolation, component terms (horizontal differences of direct and surface-reflected magnitudes and phase lag angles) along the $k_{lo}$ and $k_{hi}$ lines are given as

$$\Delta F_d^2 = F_d^2_{R_{On}^{k_{lo}}} - F_d^2_{R_{Op}^{k_{lo}}},$$
$$\Delta F_r^2 = F_r^2_{R_{On}^{k_{lo}}} - F_r^2_{R_{Op}^{k_{lo}}},$$
$$\Delta \Omega = \Omega_{R_{On}^{k_{lo}}} - \Omega_{R_{Op}^{k_{lo}}},$$

substituting the index $k_{hi}$ for $k_{lo}$ as appropriate. It should be noted that these horizontal differences need only be calculated while both $k_{hi}$ and $k_{lo}$ remain greater than or equal to both $k_{\text{minp}}$ and $k_{\text{minn}}$. If these conditions are not met, any continued difference calculations would take place within the PE region which would yield undesirable results. For failure of these conditions, the previously calculated difference values are used for the lower RO region boundary calculations.

152
c. If \( k_{lo} \) is greater than or equal to \( k_{minp} \), the horizontally interpolated direct and surface-reflected magnitudes and phase lag angles along the \( k_{lo} \) line can proceed in a forward manor (from \( x_{ROP} \) to \( r_{out} \)). These values are given as

\[
F_{d_{lo}}^2 = F_{d_{ROP \cdot k_{lo}}}^2 + \text{ratio} \Delta F_{d_{lo}}^2, \\
F_{r_{lo}}^2 = F_{r_{ROP \cdot k_{lo}}}^2 + \text{ratio} \Delta F_{r_{lo}}^2, \\
\Omega_{lo} = \Omega_{ROP \cdot k_{lo}} + \text{ratio} \Delta \Omega_{lo}.
\]

In a like manor, the same three equations above are used to get the values along the \( k_{hi} \) line by substituting the index \( k_{hi} \), assuming, however, \( k_{hi} \) is also greater than or equal to \( k_{minp} \). Should either \( k_{lo} \) or \( k_{hi} \) be less than \( k_{minp} \), the interpolation must proceed in a backward manor (from \( x_{ROn} \) to \( r_{out} \)). The above three equations may again be used by substituting the index \( i_{ROn} \) for \( i_{ROP} \) and the value \((1 - \text{ratio})\) for \( \text{ratio} \).

2. Once the horizontal interpolation of magnitudes and phase lag angles has been accomplished, the vertical interpolation of magnitudes and phase lag angles at the APM output point may proceed as

\[
F_{d_{lo}}^2 = F_{d_{lo}}^2 + \text{ratio}_k (F_{d_{hi}}^2 - F_{d_{lo}}^2), \\
F_{r_{lo}}^2 = F_{r_{lo}}^2 + \text{ratio}_k (F_{r_{hi}}^2 - F_{r_{lo}}^2), \\
\Omega = \Omega_{lo} + \text{ratio}_k (\Omega_{hi} - \Omega_{lo}),
\]

Where \( \text{ratio} \) from \( k_{lo} \) to \( k_{hi} \) is

\[
\text{ratio}_k = \frac{1000 \ zr_{oj}}{r_{out} - k_{lo}}.
\]

3. From the magnitudes of the direct and surface-reflected components and the phase lag angle, the square of the propagation factor at the APM output point is given as

\[
F^2 = \left| F_{d_{lo}}^2 + F_{r_{lo}}^2 + 2 \sqrt{F_{d_{lo}}^2 F_{r_{lo}}^2} \cos \Omega \right|,
\]

which, in turn, is converted to a propagation factor expressed in decibels by

\[
F_{dB} = 10 \log_{10} \left[ \max \left( F^2, 10^{-25} \right) \right].
\]
4. Finally, the total propagation loss and propagation factor is computed at the \( j^{th} \) APM output point and converted to centibels accordingly:

\[
L_{db} = fsl_{isp} - F_{db} + gas_{loss},
\]

\[
F_{db} = fsl_{isp} - L_{db},
\]

\[
mpfl_{1,j} = \text{NINT}(10L_{db}),
\]

\[

5.2.17 Save Profile (SAVEPRO) SU

The purpose of the SAVEPRO SU is to store the gradients and heights of the current refractivity profile, upon each reference to the FZLIM SU, from the top of the PE calculation region to the maximum user-specified height.

Upon entering, the current profile height array \(htdum\) is searched to find the index \(i\) such that \(htdum_i\) is the first height in the profile that is greater than the maximum PE calculation height, \(z_{lim}\). The counter \(l_{new}\) is then initialized to -1.

Next, the gradients are calculated and stored, along with corresponding heights, as follows

\[
\text{grad}_{l_{new},iz} = \frac{\text{refdum}_{j+1} - \text{refdum}_j}{htdum_{j+1} - htdum_j},
\]

\[
ht_{l_{new},iz} = htdum_j,
\]

where \(j\) is incremented by one from \(i\) to \(lvlep-1\), \(l_{new}\) is incremented by one with each increment in \(j\), and \(iz\) represents the range step index for XO calculations.
Before exiting, the last height level in \( htdum \) is stored and the final number of levels, \( l_{new} \), in the \( iz^{th} \) profile (represented by \( \text{grad} \) and \( htr \)) is stored in array \( lvl \).

Table 96 and Table 97 identify, describe the purpose for, state the units of, and show the computational source for each input and output data element, respectively, of the SAVEPRO SU.

#### 5.2.18 Spectral Estimation (SPECEST) SU

The purpose of the SPECEST SU is to determine the outward propagation angle at the top of the PE calculation region or the grazing angle at the lower part of the PE region based on spectral estimation. The outward propagation angle is used for XO calculations and the grazing angle is used for rough surface calculations.

Upon entering the SPECEST SU, if the outward propagation angle is to be determined (\( i_{flag} = 0 \)), the topmost \( n_p \) points (within the unfiltered portion) of the complex PE field are separated into their real and imaginary components, \( xp \) and \( yp \), respectively. If the grazing angle is to be determined (\( i_{flag} = 1 \)), then the lowest \( n_p \) points of the complex PE field are used. A window filter is then applied to both real and imaginary component arrays by multiplying each element in \( xp \) and \( yp \) by each corresponding element in the filter array \( filtp \) for indices between \( \frac{3}{4} n_p \) and \( n_p \).
Next, the array elements in \( xp \) and \( yp \) are set to 0 for indices from \( n_p+1 \) to \( n_s-1 \). [Note that both \( xp \) and \( yp \) are arrays of size \( n_s \).] The DRST SU is then referenced to obtain the spectral field components.

The spectral amplitudes in dB are then given by

\[
spectr_i = 10 \log_{10} \left[ \max \left( 10^{-10}, \sqrt{xp_i^2 + yp_i^2} \right) \right]; \quad i = 0, 1, 2, ..., n_s - 1.
\]

Next, a 3-point average is performed on \( spectr \) to determine the bin, or index \( i_{peak} \), at which the peak spectral amplitude occurs. Once \( i_{peak} \) has been determined, the outward propagation angle is calculated as

\[
\theta_{out} = \sin^{-1} \left( \frac{\lambda} {2 n_s \Delta z_{PE}} \right).
\]

Table 98 and Table 99 identify, describe the purpose for, state the units of, and show the computational source for each input and output data element, respectively, of the SPECEST SU.

5.2.19 Troposcatter (TROPOSCAT) SU

The purpose of the TROPOSCAT SU is to calculate loss due to troposcatter and determine the appropriate loss to add to the already calculated propagation loss at and beyond the radio horizon.

Upon entering the TROPOSCAT SU, the current output range $r_{out}$ is updated, and the surface refractivity and associated variables are also initialized. The surface refractivity $s_{n_{ref}}$ is initialized accordingly:

$$s_{n_{ref}} = \frac{1}{2} (s_{n_{ref}} + r_{ref})$$

A term used in the troposcatter transmission loss calculation, $s_{n_1}$, is determined from

$$s_{n_1} = 0.031 - 0.00232 s_{n_{ref}} + 5.67 \times 10^{-6} s_{n_{ref}}^2$$

along with a loss term $t_{lst_s}$ for smooth surface as

$$t_{lst_s} = t_{lst_{wr}} - 0.2 s_{n_{ref}}$$

Next, the tangent angle from the source to the surface, $\vartheta_1$, is initialized to its value for smooth surface, $\vartheta_s_1$, and the troposcatter loss term $t_{lst}$ is initialized to its value for smooth surface, $t_{lst_s}$.

If performing a terrain case ($f_{ier}$ = ‘.true.’), the index $j_{i2}$ is initialized where the first occurrence of the condition $j_{i2} \Delta r_{PE} > r_{out}$ is met. The index $j_{i1}$ is set equal to the index location within $\vartheta_{I_i}$, up to $j_{i2} - 1$, where the minimum value occurs. The tangent angle from the source height $\vartheta_i$ is then initialized to $\vartheta_{I_{j1}}$ and the corresponding range $d_1$ is initialized $j_{i1} \Delta r_{PE}$.

The following steps 1 through 13 are performed for each output height index $j$ from $j_s$ to $j_e$. 
1. If running a smooth surface case ($f_{\text{ter}} = \text{false}$) and $r_{\text{out}}$ is less than the minimum range $rd_{ij}$ at which diffraction field solutions are applicable for the current height, then the SU is exited. Otherwise, the SU program flow continues with step 2.

2. The tangent angle from the receiver, $\vartheta_2$, is initialized to that for the $j^{th}$ receiver height over smooth surface, $\vartheta_2^{sj}$. However, if $f_{\text{ter}} = \text{true}$, then the largest tangent angle $a_2$ and range $d_2$ from the receiver to the tangent point are determined using an iterative loop performed for index $i$ from $j_{12}-1$ to $j_{11}$ in decrements of -1 as follows:

\[
\begin{align*}
  r_2 &= r_{\text{out}} - i \Delta r_{PE} \\
  a_2 &= \frac{z_{\text{out}} - tyh_i + r_2}{twoka},
\end{align*}
\]

If the current $\vartheta_2$ value is less than $a_2$, then $\vartheta_2$ is set equal to $a_2$ and $d_2$ is set equal to $r_2$. The index $i$ is decremented by one, and the above calculations are repeated.

3. Once the loop in step 2 is been completed, the final value of $\vartheta_2$ is checked. If it is greater than the tangent angle for smooth surface $\vartheta_2^{sj}$ (at the same receiver range), then both $\vartheta_2$ and $d_2$ are set equal to $\vartheta_2^{sj}$ and $d_2^{sj}$, respectively.

4. Next, if $r_{\text{out}}$ is less than the sum of the tangent ranges, $d_1$ and $d_2$, then the SU is exited. Otherwise, SU program flow continues with step 5.

5. To account for antenna pattern effects over terrain, the ANTPAT SU is referenced using the tangent angle from the source to determine the antenna pattern factor, $f(\vartheta_1)$. The troposcatter loss term is then adjusted from its smooth surface value as

\[
tlst = \lnst - 20 \log_{10} \left[ f(\vartheta_1) \right].
\]

The following steps 6 through 13 are now performed regardless of the value of $f_{\text{ter}}$.

6. The common volume scattering angle is given by

\[
\theta = \vartheta_{0_{\text{up}}} - \vartheta_1 - \vartheta_2.
\]

7. Next, the following calculations are made to determine the effective scattering height $h_o$: 
\[
\begin{align*}
\alpha &= \frac{1}{2} \vartheta_{0_{\text{isp}}} - \vartheta_1 + \frac{\text{adif}_j}{r_{\text{out}}}, \\
\beta &= \frac{1}{2} \vartheta_{0_{\text{isp}}} - \vartheta_2 - \frac{\text{adif}_j}{r_{\text{out}}}, \\
s &= \text{MIN}\left(\text{MAX}\left(0.1, \frac{a}{b}\right), 10\right), \\
h_o &= \frac{s \ r_{\text{out}} \ \theta}{10^3 (1 + s^2)}. \\
\end{align*}
\]

8. The parameter \( \eta_s \) is then calculated as a function of \( h_o \):

\[
\begin{align*}
\eta_{ss} &= .5696 \ h_o \left(1 + s n_1 e^{-3.8 \times 10^{-6} h_o^6}\right), \\
\eta_s &= \text{MIN}(\text{MAX}(0.1, \eta_{ss}), 5).
\end{align*}
\]

9. Next, the parameters \( ct_1 \) and \( ct_2 \) are defined as

\[
\begin{align*}
ct_1 &= 16.3 + 13.3 \eta_s, \\
ct_2 &= 4 + 16 \eta_s,
\end{align*}
\]

where these are in turn used to calculate the quantities \( r_1 \) and \( r_2 \):

\[
\begin{align*}
r_1 &= \text{MAX}(0.1, r_1 \theta), \\
r_2 &= \text{MAX}(0.1, r_j \ zout_j \ \theta).
\end{align*}
\]

The quantity \( r_f \) was previously determined by referencing the TROPOINIT SU.

10. \( ct_1, ct_2, r_1, \) and \( r_2 \) are next used to determine \( H_1 \) and \( H_2 \):

\[
\begin{align*}
H_1 &= \text{MAX}\left[0, ct_1 \ (r_1 + ct_2)^{1/3}\right], \\
H_2 &= \text{MAX}\left[0, ct_1 \ (r_2 + ct_2)^{1/3}\right].
\end{align*}
\]

11. The frequency gain function \( H_o \) is then determined by

\[
H_o = \frac{H_1 + H_2}{2} + \Delta H_o
\]

where
\[ \Delta H_o = 6 \log_{10} \left( \frac{n_o}{n_r} \right) \log_{10}(s) \log_{10}(q_r), \]
\[ q_r = \min \left[ 10, \max \left( 0.1, \frac{\sqrt{2}}{s r_l} \right) \right]. \]

\( \Delta H_o \) is not allowed to be larger than \( \frac{1}{2}(H_1 + H_2) \) and \( H_o \) is set equal to 0 if it becomes negative.

12. Next, the troposcatter loss is computed from

\[ t_{\text{loss}} = tlst + 573 \theta + r \log_{10} \theta + H_o. \]

13. Finally, through a method of “bold interpolation” the propagation loss \( r_{\text{loss}} \), previously computed in the CALCLOS SU, is adjusted for loss due to troposcatter according to

\[ L_{\text{diff}} = r_{\text{loss}} - t_{\text{loss}}, \]
\[ r_{\text{loss}} = t_{\text{loss}} \quad \text{for } L_{\text{diff}} \geq 18 \text{ dB}, \]
\[ r_{\text{loss}} = r_{\text{loss}} - 10 \log_{10} \left( 1 + 10^{0.1 L_{\text{diff}}} \right) \quad \text{for } L_{\text{diff}} \geq -18 \text{ dB}. \]

Table 100 and Table 101 identify, describe the purpose for, state the units of, and show the computational source for each input and output data element, respectively, of the TROPOSCAT SU.

5.3 EXTENDED OPTICS INITIALIZATION (XOINIT) CSC

The purpose of the XOINIT CSC is to initialize the range, height, and angle arrays in preparation for XO calculations.

Upon entering the XOINIT CSC, the value of \( i_{\text{xostp}} \) is tested. If \( i_{\text{xostp}} \) is equal to 0, then the APMCLEAN SU is referenced to deallocate all arrays used in the APM application and the CSC is exited. If \( i_{\text{xostp}} \) is greater than 0, then the following procedure is performed.
The arrays \textit{curang} and \textit{curng}, used for storage of traced local angles and ranges, respectively, are allocated and initialized to the range and angle values stored in \textit{ffacz}. The array \textit{curht} is allocated and initialized to the height of the top of the PE calculation region, \textit{zlim}. The array \textit{igrd}, used for storage of starting refractivity gradient level (at which to begin ray tracing), is allocated and initialized to 0. The 2-dimensional array \textit{prfhxo}, containing final output heights and propagation factors, along with the dummy array \textit{dum}, used for temporary storage, are also allocated and initialized to 0.

If \textit{fter} is \texttt{.true.}, then the MEANFILT SU is referenced twice to perform a 9-point smoothing operation on the angle values, using \textit{dum} for temporary storage of angles after the first pass smoothing operation. Next, the starting height index at which to begin XO calculations, \textit{jxstart} is initialized to the ending height index for PE calculations, \textit{jend}, plus one. Finally, \textit{dum} is deallocated before exiting.

Table \ref{tab:xoinit-input} and Table \ref{tab:xoinit-output} identify, describe the purpose for, state the units of, and show the computational source for each input and output data element, respectively, of the XOINIT CSC.

5.3.1 APM Clean (APMCLEAN) SU

The purpose of the APMCLEAN SU is to deallocate all dynamically dimensioned arrays used in one complete run of APM calculations.

Upon entry, all arrays that were dynamically allocated at the beginning of the current application are now deallocated.

Table 104 and Table 105 identify, describe the purpose for, state the units of, and show the computational source for each input and output data element, respectively, of the APMCLEAN SU.

5.3.2 Mean Filter (MEANFILT) SU

The purpose of the MEANFILT SU is to perform a $i_{xc}$-point average smoothing operation on the array passed to it.

The array $arbef$ is passed to the SU, along with the number of points over which to perform the smoothing operation, $i_{xc}$. Once the smoothing operation has been performed, the resulting “smoothed” points are stored in $araft$ and passed back to the calling routine. The operation is performed as follows:
\[
ar_{\text{after}}_k = \frac{1}{m} \sum_{i=k}^{k+m'} \text{arbef}_i \quad \text{for } k = m' + 1, m' + 2, \ldots, i_{sz} - m'
\]

where \(m'\) is \(\frac{1}{2}(m-1)\) and \(m\) is the size of array \(\text{arbef}\).

Table 106 and Table 107 identify, describe the purpose for, state the units of, and show the computational source for each input and output data element, respectively, of the MEANFILT SU.

### 5.4 EXTENDED OPTICS STEP (XOSTEP) CSC

The purpose of the XOSTEP CSC is to calculate the propagation loss in the XO region for one output range step.

Upon entering the XOSTEP CSC, the current execution mode is checked to determine if XO calculations will be necessary \((i_{\text{hybrid}} \neq 0)\). If \(i_{\text{hybrid}}\) is 0, then the CSC is exited.

If \(i_{\text{hybrid}}\) is not equal to 0, the output range \(r_{\text{outs}}\) and the gaseous absorption loss \(\text{gas}_{\text{loss}}\) are updated. The \(mpfl\) values are initialized to -1000 from the index of the start of XO calculations, \(j_{\text{start}}\), to the maximum number of height output points, \(n_{\text{out}}\). The EXTO SU is then referenced to calculate propagation factor and loss values in the XO region. Propagation factor and loss values are returned in \(mpfl\) from index \(j_{\text{start}}\) to \(j_{xe}\).

If FE and RO calculations need to be performed \((i_{\text{hybrid}} = 1)\), then the indices \(j_{fs}\) and \(j_{fe}\), indicating the height index at which to start and end FE calculations, respectively, are determined. The FEM SU is then referenced to compute propagation factor and loss
values for heights \( z_{out_{j_k}} \) to \( z_{out_{j_f}} \). Similarly for RO calculations, the indices \( j_{rs} \) and \( j_{re} \) are determined, and the ROLOSS SU is referenced to compute propagation factor and loss values for heights \( z_{out_{j_{rs}}} \) to \( z_{out_{j_{re}}} \).

Finally, the index \( j_{xend} \) is set equal to the maximum of \( j_{xe}, j_{fe}, \) and \( j_{re} \). If the last range value has been reached (\( istp = n_{rout} \)) then the APMCLEAN SU is referenced to deallocate all arrays allocated for the APM application.

Table 108 and Table 109 identify, describe the purpose for, state the units of, and show the computational source for each input and output data element, respectively, of the XOSTEP CSC.

**5.4.1 Extended Optics (EXTO) SU**

The purpose of the EXTO SU to calculate propagation factor and loss based on XO techniques. The SU performs a ray trace on all rays within one output range step and returns the propagation factor and loss up to the necessary height; storing all angle, height, and range information for subsequent ray tracing upon the next reference to the SU.

Upon entering the SU, internal one-line ray trace functions are defined as

\[
\text{RADA} \, I(a,b) = a^2 + 2g_{rd}b, \\
\text{RP}(a,b) = a + \frac{b}{g_{rd}}, \\
\text{AP}(a,b) = a + bg_{rd}, \\
\text{HP}(a,b,c) = a + \frac{b^2 - c^2}{2g_{rd}}.
\]

Next, the starting and ending index counters \(iz_s, iz_e\), respectively, for the local angle, range, and height arrays, and the refractivity profile starting index \(i_{rps}\) are initialized to 1 for the first reference to the EXTO SU. The index \(iz_e\) is then determined such that \(\text{curng}_{iz_e} \leq r_{out} < \text{curng}_{iz_e+1}\). The integer counter \(k\), indicating the number of propagation factor and heights in array \(prfhxo\), is initialized to 0.

The following ray trace steps 1 through 3 are performed for each ray; i.e., for each \(j^{th}\) angle, range, and height triplet, for \(j\) ranging from \(iz_s\) to \(iz_e\).

1. At the start of the ray trace, the current local angle \(a_0\), range \(r_0\), height \(h_0\), and refractive gradient index \(i_{grad}\) are initialized to \(\text{curang}_j, \text{curng}_j, \text{curht}_j, \text{andigrd}_j\), respectively. Next, refractive profile index, \(i_{rps}\), is initialized to the maximum of \(j\) or \(i_{rps}\). Finally, the refractivity gradient, \(g_{rd}\) is set equal to the gradient at the \(i_{grad}\) level of the \(i_{rps}\) profile, \(\text{grad}_{igrad_{i_{rps}}}\). The following ray trace steps 1.a through 1.d are then performed until the current local range \(r_0\) becomes greater than or equal to \(r_{out}\).

   a. The ending range, \(r_1\), in the ray trace segment is set equal to the minimum of \(ffacz_{i_{rps}+1,2}\) or \(r_{out}\). If \(i_{rps}\) is equal to the number of stored triplets, \(iz\), then \(r_1\) is set equal to \(r_{out}\).

   b. The \(j^{th}\) ray is then traced to \(r_1\) and the resulting angle and height at the end of the segment is determined via the in-line functions as

\[
a_i = \text{AP}(a_0, r_1 - r_0), \\
h_i = \text{HP}(h_0, a_i, a_0).
\]
c. The ending height \( h_1 \) is then compared to the next height level in the current refractivity profile, \( h_{trigrad+1,irp} \), and if \( h_1 \) is greater than this height level, it is set equal to \( h_{trigrad+1,irp} \) and a new \( a_1 \) and \( r_1 \) are computed from

\[
\begin{align*}
    a_1 &= \sqrt{\text{RADA}1(a_0, h_1 - h_0)} \\
    r_1 &= \text{RP} \left( n_0, a_1 - a_0 \right)
\end{align*}
\]

\( i_{grad} \) is then set to the minimum of \( i_{grad+1} \) or \( lvl_{irp-1} \).

d. The starting angle, range, and height for the next ray trace segment is updated, and, if necessary, the refractivity profile index \( irp \) is updated to the minimum of \( irp+1 \) or \( iz_e \). Steps 1.a through 1.d are then repeated for the next ray segment.

2. Once the ray has been traced to a range of \( r_{out} \) or greater, the current angle, range, and height arrays, \( curang, curng, \) and \( curht \), respectively, are updated to the values for \( a_0, r_0, \) and \( h_0 \) for subsequent references to the EXTO SU.

3. The counter \( k \) for the propagation factor and height array is incremented by one and the array is updated according to

\[
\begin{align*}
    prfhxo_{k,1} &= ffacz_{j,1} \\
    prfhxo_{k,2} &= h_0
\end{align*}
\]

Once all rays have been traced, the starting profile index \( irps \) is updated to \( iz_e \) for the next reference to the EXTO SU, and the counter \( k \) is again incremented by one and the last values of \( prfhxo \) updated as follows,

\[
\begin{align*}
    prfhxo_{k,1} &= ffout_{isp,1} \\
    prfhxo_{k,2} &= ffout_{isp,2}
\end{align*}
\]

The number of traced XO height points, \( n_{xo} \), at the current output range is then set to \( k \). Note that at this point, all output heights in \( prfhxo_{0:n_{xo}} \) are decreasing from \( prfhxo_{1,2} \) to \( prfhxo_{n_{xo}} \) and all traced heights in \( curht \) are decreasing from \( curht_{iz_s} \) to \( curht_{iz_e} \).

The starting index \( iz_s \) is then adjusted (for the next reference to the EXTO SU) if the topmost traced height \( curht_{iz_s} \) is greater than \( h_{lim} \). If performing a terrain case, the output height points may not be continually decreasing from \( prfhxo_{1,2} \) to \( prfhxo_{n_{xo}} \). In this case, \( prfhxo \) is sorted such that all height values are steadily decreasing. The ending index, \( j_{xe} \), at which XO propagation factor and loss values will be calculated and stored in
mpfl, is set equal to $n_{z_{out}}$ and adjusted, if necessary, such that $z_{out_{ix}}$ is less than $prfhxo_{1,2}$. Now, the counter index $ix$ is initialized to $n_{xo}$. Next, the propagation factor is determined via linear interpolation on the values in $prfhxo$. The following steps 1 through 2 are performed for each output height point $z_{out_j}$ for $j$ varying from $j_{xs}$ to $j_{xe}$.

1. The counter $ix$ is adjusted (if necessary) such that $prfhxo_{ix,2} \leq z_{out_j} < prfhxo_{ix-1,2}$.

2. The propagation factor $F_{dB}$ and propagation loss $rloss$ at height $z_{out_j}$ are then calculated according to

$$F_{dB} = prfhxo_{ix-1,1} + \left( prfhxo_{ix,1} - prfhxo_{ix-1,1} \right) \frac{z_{out_j} - prfhxo_{ix,2}}{prfhxo_{ix-1,2} - prfhxo_{ix,2}} ,$$

$$rloss_j = fsl_{ix} - F_{dB}$$

Once all propagation loss values have been computed, the TROPOSCAT SU is referenced to compute troposcatter loss, if necessary. Finally, the loss due to gasesous absorption is added to $rloss$ and then converted to centibels and stored in $mpfl$ before exiting.

Table 110 and Table 111 identify, describe the purpose for, state the units of, and show the computational source for each input and output data element, respectively, of the EXTO SU. Table 112 identifies terms which are used internal to the EXTO SU and whose value must be retained from SU call to SU call for reasons of computational efficiency.

6. REQUIREMENTS TRACEABILITY

This section provides the traceability of the design of the APM CSCI. Table 113 presents this traceability between the corresponding sections of the Software Requirements Specification (SRS) and the Software Design Description (SDD) and between the various components of the APM CSCI.

Table 113. Traceability matrix between the SRS and the SDD.

7. NOTES

7.1 APM CSCI IMPLEMENTATION AND APPLICATION CONSIDERATIONS

The calling NITES CSCI application will determine the employment of the APM CSCI. However, the intensive computational nature of the APM CSCI must be taken into consideration when designing an efficient calling application. For this reason, the APM CSCI is designed with flexibility for various hardware suites and computer resource management considerations. This APM CSCI applies only to a coverage and loss diagram application. The following highly recommended guidelines are provided to aid in the design of a coverage or loss diagram application which will most efficiently employ the APM CSCI.

The APM CSCI propagation loss calculations are independent of any target or receiver considerations; therefore, for any EM emitter, one execution of the APM CSCI may be used to create both a coverage diagram and a loss diagram. Since both execution time and computer memory allocation should be a consideration when employing this model, it is most efficient and appropriate to execute the APM CSCI for a particular EM system/environmental/terrain combination before executing any application. The output of the APM CSCI would be stored in a file which would be accessed by multiple applications.

For example, the NITES operator may desire a coverage diagram for one particular radar system. At the beginning of the coverage diagram application, a check would be made for the existence of a previously created APM CSCI output file appropriate for the EM system, environmental, and terrain conditions. If such a file exists, the propagation loss values would be read from the file and used to create the coverage diagram. If the file does not exist, the APM CSCI would be executed to create one. As the APM CSCI is executing, its output could be routed simultaneously to a graphics display device and a file. This file could then be used in the loss diagram application should the operator also choose it. Two distinct applications, therefore, are achieved with only one execution of the APM CSCI. Additionally, should the operator desire an individual coverage diagram for each of multiple targets, or a single coverage diagram illustrating radar detection of a low-flying missile superimposed upon a coverage diagram illustrating his own radar's vulnerability as defined by the missile's ESM receiver, only a single execution of the APM CSCI would be required, thereby saving valuable computer resources.

7.2 ENVIRONMENTAL RADIO REFRACTIVITY FIELD DATA ELEMENTS

The radio-refractivity field, i.e., the profiles of M-units versus height, should consist of vertical piece-wise linear profiles specified by couplets of height in meters with respect to mean sea level and modified refractivity (M-units) at multiple arbitrary ranges. All vertical profiles must contain the same number of vertical data points, and be
specified such that each numbered data point corresponds to like-numbered points (i.e., features) in the other profiles. The first numbered data point of each profile must correspond to a height of zero mean sea level and the last numbered data point must correspond to a height such that the modified refractivity for all greater heights is well represented by extrapolation using the two highest profile points specified.

With the inclusion of terrain and allowing the terrain profile to fall below mean sea level, refractivity profiles can also be provided in which the first level is less than 0 (or below mean sea level). For a terrain profile that falls below mean sea level at some point, the assumption is that the minimum height may be less than the first height in any refractivity profile specified. Therefore, an extrapolation flag, \( i_{extra} \), must be specified to indicate how the APM CSCI should extrapolate from the first refractivity level to the minimum height along the terrain profile. Setting \( i_{extra} \) to 0 will cause the APM CSCI to extrapolate to the minimum height using a standard atmosphere gradient; setting \( i_{extra} \) to 1 will cause the APM CSCI to extrapolate to the minimum height using the gradient determined from the first two levels of the refractivity profile.

Within each profile, each numbered data point must correspond to a height greater than or equal to the height of the previous data point. Note that this requirement allows for a profile which contains redundant data points. Note also that all significant features of the refractivity profiles must be specified, even if they are above the maximum output height specified for a particular application of APM.

The NITES CSCI application designer and the NITES operator share responsibility for determining appropriate environmental inputs. For example, a loss diagram may be used to consider a surface-to-surface radar detection problem. Since the operator is interested in surface-to-surface, he may truncate the profile assuming that effects from elevated ducting conditions are negligible. It may be, however, that the elevated duct does indeed produce a significant effect. The operator should ensure, therefore, that the maximum height of the profile allows for the inclusion of all significant refractive features.

This specification allows a complicated refractivity field to be described with a minimum of data points. For example, a field in which a single trapping layer linearly descends with increasing range can be described with just two profiles containing only four data points each, frame (a) of Figure 3. In the same manner, other evolutions of refractive layers may be described. Frames (b) and (c) of Figure 3 show two possible scenarios for the development of a trapping layer. The scenario of choice is the one which is consistent with the true thermodynamical and hydrological layering of the atmosphere.
Two external implementation data variables applicable to both the NITES operator and to the calling application designer are $r_{\text{max}}$, the maximum APM CSCI output range, and $h_{\text{max}}$, the maximum APM CSCI output height. These two parameters are required by the APM CSCI to determine the horizontal and vertical resolution, respectively, for internal range and height calculations based on the current values of $n_{\text{rout}}$ and $n_{\text{zout}}$. Any value of $r_{\text{max}}$ and $h_{\text{max}}$ is allowed for the convenience of the NITES operator and the calling application designer, provided $r_{\text{max}} \geq 5 \text{ km}$, and $h_{\text{max}} \geq 100 \text{ m}$. For example, the NITES operator may desire a coverage diagram which extends to a range of 500 kilometers (km). In addition to accommodating the desires of the operator, specification of such a convenient maximum range eases the burden for the application designer in determining incremental tick marks for the horizontal axis of the display.

Provided the value of the parameter $lerrl2$ is set to `false.', if the furthest environment profile range is less than $r_{\text{max}}$, the APM CSCI will automatically create an environment profile at $r_{\text{max}}$ equal to the last profile specified, making the environment homogeneous from the range of the last profile specified to $r_{\text{max}}$. For example, a profile is input with an accompanying range of 450 km. If the NITES operator chooses an $r_{\text{max}}$ of...
500 km, the APM CSCI will continue loss calculations to 500 km, keeping the refractivity environment homogeneous from 450 km to 500 km.

If \textit{lerr12} is set to '.true.' and the furthest environment profile range is less than \( r_{\text{max}} \), then an error will be returned in \( i_{\text{error}} \) from the APMINIT CSC. This is to allow the NITES CSCI application designer greater flexibility in how environment data is handled.

### 7.3 TERRAIN PROFILE DATA ELEMENT

The terrain profile should consist of linear piece-wise segments specified in terms of range/height pairs. All range values must be increasing, and the first terrain height value must be at range zero. General ground composition types can be specified (Table 4), along with corresponding ranges over which the ground type is to be applied. If ground type “User Defined” is specified (\( i_{\text{grnd}_i} = 7 \)), then numeric values of relative permittivity and conductivity must be given. If horizontal antenna polarization is specified, the APM CSCI will assume perfect conductivity for the entire terrain profile and will ignore any information regarding ground composition. If vertical antenna polarization is specified, then information regarding ground composition must also be specified.

The maximum height, \( h_{\text{max}} \), must always be greater than the minimum height, \( h_{\text{min}} \). Also, a value of \( h_{\text{max}} \) must be given such that it is larger than the maximum elevation height along a specified terrain profile.

Provided \textit{lerr6} is set to '.false.', if the furthest range point in the terrain profile is less than \( r_{\text{max}} \), the APM CSCI will automatically create a height/range pair as part of the terrain profile at \( r_{\text{max}} \) with elevation height equal to the last height specified in the profile, making the terrain profile flat from the range of the last profile point specified to \( r_{\text{max}} \). For example, a terrain profile is input where the last height/range pair is 50 meters (m) in height with an accompanying range of 95 km. If the NITES operator chooses an \( r_{\text{max}} \) of 100 km, the APM CSCI will continue loss calculations to 100 km, keeping the terrain profile flat from 95 km to 100 km with an elevation height of 50 m.

If \textit{lerr6} is set to '.true.' and the furthest range point is less than \( r_{\text{max}} \), then an error will be returned in \( i_{\text{error}} \) from the APMINIT SU. This is to allow the NITES CSCI application designer greater flexibility in how terrain data is handled.

#### 7.5 SDD VARIABLE NAME, FORTRAN VARIABLE NAME CROSS REFERENCE

The following table, Table 115, is a cross reference of variable names used within the body of this document and the FORTRAN variable names as used within the APM CSCI source code of Section 8, Appendix A. Included are the SDD variable name, its description, the FORTRAN source code name, and the designation of the FORTRAN COMMON BLOCK name, if applicable. Note – all dynamically allocated arrays are declared PUBLIC and are common to all SUs containing the APM_MOD module.
Table 115. Variable name cross reference.

APPENDIX A
FORTRAN SOURCE CODE FOR APM CSCI

A.1 SUBROUTINE APMINIT

! Version 1.3.1
! Author: Amalia E. Barrios
! SPAWARSYSCEN SAN DIEGO D858
! 49170 Propagation Path
! San Diego, CA 92152-7385
! e-mail: barrios@spawar.navy.mil
! phone: (619) 553-1429
! fax: (619) 553-1417

! Summary: These routines model tropospheric radiowave propagation over
! variable terrain and calculates propagation loss vs. height and
! range. Propagation loss is displayed in dB contours on a height vs.
! range plot. APM is based on the Radio Physical Optics (RPO) model
! developed by Herb Hitney (SPAWARSYSCEN SAN DIEGO) and the Terrain
! Parabolic Equation Model (TPEM) developed by Amalia Barrios
! (SPAWARSYSCEN SAN DIEGO). The parabolic equation sub-model is based
! on the split-step Fourier PE method and was originally developed
! from an early PE model called PEPC, written by Fred Tappert.

! Propagation loss over variable terrain is modeled by shifting
! the field an appropriate number of bin widths correspond-
! ing to the height of the ground. The field is determined using the
! smooth earth PE method. A hybrid capability is also included for
! limited cases (low antenna heights and/or initial flat terrain).
! The hybrid model consists of a flat earth (FE) region at very high
! angles, a ray-optics (RO) model at intermediate angles, and
! the split-step PE model below the lowest RO angle. An extended
! optics model (XO) is used at heights above the FE region
! and at ranges beyond the RO region.

! Variables in small letters in parameter lists are variables that are input
! or passed to called subroutines. Variables in CAPS in parameter lists are
! returned from the called subroutines.

! ***************************************************************************

! SUBROUTINE APMINIT

! Module Name: APMINIT

! Module Security Classification: UNCLASSIFIED

! Purpose: Initializes all variables used in APM subroutines for FE, RO,
! and PE calculations. After initial units conversions have been
! done, all calculations are in metric units. Height and range
! values are in meters and angles are in radians.

! Version Number: 1.3.1

! INPUTS:
! ! Argument List: NONE
! ! Common: ABSHUM, ANHT, BWIDTH, ELEV, FREQ, GAMMAA, HMAX, HMIN, IGR, IPAT,
! ! IPOP, ITP, NW, LERR6, LERR12, LVLP, NFACS, NPROF, NROUT, NW,
! ! NZOUT, PEFLAG, RMAX, TAIR, THMAX, TROPO
! ! Public: DIELEC(,), HRFANG(), HFFAC(), HMLSL(,), IGRND(), REFMSL(,), RGRND(,
! ! RMPROF(,), RNGWIND(,), TERX(), TERY(), WIND()
! ! Parameters: PI
! ! Data: C0, DEG5, ISM, RADC, RTST

! OUTPUTS:
! ! Argument List: IXOSTP, IERROR
! ! Common: Most variables in common block APM_VAR
! ! Public: All public arrays.
! Modules Used: APM_MOD

! Calling routines: MAIN DRIVER PROGRAM

! Routines called:
!   APM Specific: ALLARRAY_APM, ALLARRAY_FE, ALLARRAY_RO, ALLARRAY_XORUF,
!                 ALN_INIT, DIEINIT, FFTPAR, FILLHT, GASABS, GET_K, GETGRAZE,
!                 GETMODE, GETTHMAX, GRAZE_INT, INTPROF, PROFINIT, PROPREF,
!                 REFINIT, REMDUP, TERINIT, TROPOINIT
!   Intrinsic: ALLOCATE, ALLOCATED, ANY, DCOS, DABS, DATAN, DBLE, DEALLOCATE,
!              DLOG10, DMAX1, DMIN1, DSIGN, DSIN, DSQRT, IDINT, IDNINT, MAX0, MIN0

! GLOSSARY: See universal glossary for common variables, data variables
!           public arrays, and parameters.

! Input Variables: NONE

! Output Variables:
!   IXOSTP = Index of output range step at which XO model is to be applied.
!   IERROR = Integer value that is returned if any errors exist in input data:
!     -6 : Last range in terrain profile is less than RMAX.
!     (Will only return this error if error flag LERR6 is set to .TRUE.).
!     -7 : Specified cut-back angles are not increasing. This is only tested for user-defined height-finder antenna pattern.
!     -8 : HMAX is less than maximum height of terrain profile.
!     -9 : Antenna height w.r.t. msl must be less than maximum height HMAX.
!     -10 : Beamwidth is less than or equal to zero for directional antenna pattern.
!     -11 : Number of antenna pattern or power reduction factors and angles (IPAT=6 or 7) is less than or equal to 1. For IPAT=6, NFACS must be at least 1; for IPAT=7, NFACS must be at least 2.
!     -12 : Range of last refractivity profile entered (for range dependent case) is less than RMAX. (This is returned from subroutine REFINIT). Will only return this error if error flag LERR12 is set to .TRUE.).
!     -13 : Height of first level in any user-specified refractivity profile is greater than 0. First height must be at m.s.l. (0.) or <0. if below m.s.l.
!     -14 : Last gradient in any refractivity profile entered is negative. (This is returned from REFINIT).
!     -17 : Range points of terrain profile are not increasing.
!     -18 : First range point is not 0.
!     -19 : Elevation angle specified (for IPAT > 1) must be less than 10 degrees.
!     -25 : Specified PE-only flag but did not specify a maximum PE calculation angle.
!     -41 : Transmitter height is less than 1.5 m.
!     -42 : Minimum height input by user (HMIN) is greater then maximum height (HMAX).
!     -43 : Transform size is greater than 2**30. Lower antenna height or frequency. Check geometry between antenna height and any terrain features.
!     -44 : Combination of frequency and antenna beamwidth results in antenna below the surface. Increase frequency or beamwidth for valid combination. CAN OVERRIDE WITH PE-ONLY OPTION BUT MUST SPECIFY MAXIMUM PE PROPAGATION ANGLE.
!     -45 : Wind speed specified is greater than 10 m/s. CAN OVERRIDE WITH PE-ONLY OPTION BUT MUST SPECIFY MAXIMUM PE PROPAGATION ANGLE.

! Local Variables:
ALFLIM = Elevation angle of RO limiting ray in radians. Used to
initialize launch angle in GETTHMAX routine.
ANGU = Maximum tangent ray angle from source to terrain peak
along profile path.
ATEG = Tangent angle used for automatic calculation of maximum
propagation angle. Only used for modes IHYBRID = 0, 2.
DIAM = Physical antenna diameter required for specified vertical beamwidth
and frequency - used only for directional antenna patterns.
FRQG = Frequency in MHz at which to perform grazing angle calcs.
HMX = Maximum height to use when computing a maximum propagation
angle for PE calculations. Only used for modes IHYBRID=0,2.
HTERM = Maximum terrain height along profile path in meters.
HTEST = Minimum height in meters at which all trapping
refractivity features are below (includes some slop).
HTRICK = Thickness in meters of highest trapping layer from all
refractivity profiles.
HTRAP = Height of highest trapping layer in meters from all
refractivity profiles.
KABS = Integer flag indicating whether or not to compute gaseous
absorption loss. KABS=0 no absorption loss; KABS=1 compute
absorption loss based on air temperature TAIR and absolute
humidity ABSHUM; KABS=2 compute absorption loss based on specified
absorption attenuation rate GAMMAA.
RFIX = If terrain profile points are equally spaced, this is
automatically determined and range spacing is set to RFIX,
otherwise, RFIX = 0.
RFLAT = Maximum range in meters at which the terrain profile
remains flat from the source.
RMMAX = Maximum M-unit value (x10e-6) of refractivity profile at
range 0.
RMMIN = Minimum M-unit value (x10e-6) of refractivity profile at
range 0.
THETAMAX = Maximum propagation angle used in PE calcs.
THMXG = Maximum PE propagation angle for grazing angle calcs (3 degrees
+ 1/3 for filtering).
ZTEST = This is the minimum height at which the PE model must
reach in order to contain all necessary refractivity and/or
terrain features.

**A.1.7 Subroutine DIEINIT**

! ************************* SUBROUTINE DIEINIT *************************

! Module Name: DIEINIT

! Module Security Classification: UNCLASSIFIED

! Purpose: This routine calculates conductivity and permittivity
! as a function of frequency in MHz. All equations and coefficients were obtained by using a SUMMASKETCH digitizer to digitize
! the CCIR volume 5 curves on page 74. The digitized data were
! then used with TABLECURVE software to obtain the best fit
! equations and coefficients used in this subroutine. In some
! cases two sets of equations were required to obtain a decent
! fit across the 100 MHz - 100GHz range. These curves fit the
! digitized data to within 5%.

! Version Number: 1.3.0

! INPUTS:
! Argument List: NONE

A.1.9 Subroutine FILLHT

******************************************************************************
******************************************************************************
Module Name: FILLHT

Module Security Classification: UNCLASSIFIED

Purpose: Fills the array HTFE() with height values of the limiting sub-model (depending on value of IHYBRID) at each output range.
I.e., if IHYBRID = 1, then HTFE() will contain height values at each output range separating the FE region from the RO region.
If IHYBRID = 0 or 2, then HTFE() will contain those height values at each output range at which the initial launch angle has been traced to the ground or surface. These height values represent the separating region where, above that height, valid loss is computed, and below that height, 1) for IHYBRID=2, no loss is computed (outside PE angle limit; or 2) for IHYBRID=0, this separates the lower FE region from the PE region.

Version Number: 1.3.0

INPUTS:
Argument List: NONE
Common: ALAUNCH, ANTREF, DR, FTER, HMREF, HTLIM, IHYBRID, ISTART1, LVLEP
Public: GRDUM(), HTDUM(), RNGOUT(), TYH()
Data: DEG5, RTST, TAN5

OUTPUTS:
Argument List: IHMX
Public: HLIM(), HTFE()

Modules Used: APM_MOD

Calling Routines: APMINIT

Routines Called:
APM Specific: PLINT, TRACE_ROUT
Intrinsic: MAX0, MIN0, DBLE, DMAX1, DMIN1, DSQRT, IDINT

GLOSSARY:
Input Variables: See universal glossary for common variables.
Output Variables: See universal glossary for common variables.

Local Variables:
A0 = Angle at start of trace in radians.
A1 = Angle at end of trace in radians.
GRD = Gradient of current refractivity layer being traced through.
H0 = Height at start of trace in meters.
H1 = Height at end of trace in meters.
H5 = Height of 5 degree ray traced to each output range point
IQUIT = Flag to end loop.
JL = Index in indicating level in refractivity profile location of source height ANTREF.
R0 = Range at start of trace in meters.
R1 = Range at end of trace in meters.
RO = Current output range to trace to.
YAR = Height of image source.

A.1.10 Subroutine GASABS

! *************************** SUBROUTINE GASABS ***************************

! Module Name: GASABS
! Module Security Classification: UNCLASSIFIED

! PURPOSE: Computes sea-level gaseous absorption from temperature,
!          absolute humidity, and radio frequency using CCIR
!          Recommendation 676-1. This routine is good for frequencies
!          less than 57 GHz, air temperature from -20 to 40 degrees C,
!          and absolute humidity from 0 to 50 g/m3.

! Version Number: 1.3.0

! INPUTS:
!   Argument List: NONE
!   Common: ABSHUM, FREQ, TAIR

! OUTPUTS:
!   Argument List: NONE
!   Common: GASATT

! Modules Used: APM_MOD

! Calling Routines: APMINIT

! Routines called: NONE

! GLOSSARY:

! Input Variables: See universal glossary for common variables.

! Output Variables: See universal glossary for common variables.

! Local Variables:
!   FGHZ = Frequency in GHz.
!   FGHZ2 = Square of frequency in GHz.
!   GAMMAO = oxygen absorption in dB/km.
!   GAMMAW = water vapor absorption in dB/km.
SUBROUTINE gasabs

A.1.14 Subroutine GETTHMAX

! *************************** SUBROUTINE GETTHMAX ***********************
! Module Name: GETTHMAX
! Module Security Classification: UNCLASSIFIED
! Purpose: This first part of this routine performs an iterative ray
!          trace such that, upon reflection, the ray clears the highest
!          terrain peak along its path by 20%. Heights and angles of
!          this ray are stored at each output range. The 2nd part of this
!          routine determines the minimum PE propagation angle
!          necessary to meet the following criteria when using the full
!          hybrid mode (i.e., IHYBRID=1): 1) Top of the PE
!          region must contain ALL trapping layers for all refractivity
!          profiles, 2) top of PE region must be at least 20% higher than
!          highest peak along terrain profile, 3) minimum PE propagation
!          angle must be at least as large as PSILIM.
! Version Number: 1.3.1

! INPUTS:
! Argument List: ALFLIM, HTERMAX, HTEST, RFLAT, ZTEST
! Common: ANTHT, ANTREF, FREQ, FTER, HTLIM, IALG, IHYBRID, ISTART1,
!          ITPA, NROUT, RMAX, RUF, WL, YFREF, ZLIM, ZTOL
! Data: RADC
! Parameter: IRTEMP
! Public: GRDUM(), HTDUM(), RNGOUT(), SLP(), TX(), TY()

! OUTPUTS:
! Argument List: IERR, THETAMAX
! Common: ALAUNCH, HTEMP(), IAP, LN, NOPE, PSILIM, RAYA(), RPEST, RTEMP(),
! THETA75, ZMAX
! Public: HLIM()

! Modules Used: APM_MOD

! Calling Routines: APMINIT

! Routines Called:
! APM Specific: FFTPAR, TRACE_ROUT
! Intrinsic: DABS, DASIN, DBLE, DEXP, DMAX1, DMIN1, DSIGN, DSQRT, IDINT, MAX0, MIN0, REAL

! GLOSSARY: See universal glossary for common and data variables.

! Input Variables:
! ALFLIM = Elevation angle of RO limiting ray in radians. Used to
! initialize launch angle in GETTHMAX routine.
! HTERMAX = Maximum terrain height along profile path in meters.
! HTEST = Minimum height in meters at which all trapping
! refractivity features are below (includes some slop).
! RFLAT = Maximum range in meters at which the terrain profile
! remains flat from the source.
! ZTEST = Height in PE region that must be reached for hybrid model.

! Output Variables:
! IERR = Integer flag returned from call to FFTPAR.
! THETAMAX = Maximum propagation angle used in the PE model.

! Local Variables:
! A0 = Angle at start of trace in radians.
! A1 = Angle at end of trace in radians.
! AMLIM = Minimum PE angle limit, i.e., THETAMAX must be at least
! this value.
! AMXCUR = Maximum local angle along the traced ray up to ZLIM (with
! minimum limit AMLIM).
! ATEMP = Temporary THETAMAX, i.e., ATEMP = AMXCUR/.75
! B1-3 = Coefficients of polynomial to determine AMLIM.
! DRTEMP = Range step for ray tracing.
! GRD = Gradient of current refractivity layer being traced through.
! H0 = Height at start of trace in meters.
! H1 = Height at end of trace in meters.
! HMT = Used for near ranges and low antenna heights over terrain, this is a
! multiplicative factor that lowers the 20% ray clearance limit for these
! cases.
! IQUIT = Integer flag indicating to quit (IQUIT=1) tracing of
! current ray and begin again with a new launch angle.
! IRAY = Integer flag to continue raytracing (IRAY = 0) or to stop
! (IRAY = 1).
! IREF = Integer flag indicating if ray has hit surface within a range step:
! 0 = no reflection
! 1 = reflection
! JL = Index for refractivity profile - current layer being traced
! through.
! KT = Counter index for terrain profile arrays TX() and TY().
! R0 = Range at start of trace in meters.
! R1 = Range at end of trace in meters.
! SLOPE = Slope of current terrain segment.
! T1-3 = Constants used in polynomial to determine AMLIM.
! TOL = Iterative height tolerance to test if appropriate combination
! of THETAMAX, FFT size, and ZMAX has been reached to meet
! all criteria.
! YN = Height of terrain at current range for traced ray.
! YNT = Height of terrain at source.
! ZLIMT = Maximum height to trace to (includes some slop).

A.1.15 Subroutine GRAZE_INT

**************************************************************************
! Module Name: GRAZE_INT
! Module Security Classification: UNCLASSIFIED

! Purpose: Interpolates grazing angles at each PE range step based on angles
! computed from ray trace (takes precedence) and those computed from
! spectral estimation. These are used for subsequent rough surface
! calculations.

! Version Number 1.3.0

! INPUTS:
!   Argument List: RFLAT
!   Common: ACUT, ANHT, DR, DR2, DRGRZ, FTER, HMREF, IGPE, IGRZ,
!   IHYBRID, IPE, LDUCT, LEVAP, PI2, RHOR, RMAX, YFREF
!   Public: GRZ_PE(), GRZ_RAY(),
!   Data: AEKST

! OUTPUTS:
!   Argument List: IERROR
!   Common: NONE
!   Public: GRAZE()

! Modules Used: APM_MOD

! Calling Routines: APMINIT

! Routines Called:
!   APM Specific: PLINT
!   Intrinsic: ALLOCATED, MIN0, DABS, DATAN, DBLE, DEALLOCATE, DMAX1, DMIN1, IDINT,
!   SUM

! GLOSSARY: See universal glossary for common and public variables

! Input Variables: See universal glossary for common variables.
!   RFLAT = Maximum range in meters at which the terrain profile
!          remains flat from the source.

! Output Variables: See universal glossary for common or public variables.
!   IERROR = Integer value returned (non-zero) if errors occur in allocat-
!    ing or deallocating GRAZE().

! Local Variables:
!   GRZ_ANG = Interpolated grazing angle.
!   ICR = Number of grazing angles from ray trace within range interval R-DR2 to
!    R+DR2.
!   PER = Range at which grazing angles from PE spectral estimation [GRZ_PE()]
!    will be included in interpolation loop.
!   R = Current PE range in meters.
!   REND = Range of end of skip zone if one exists.
!   RGRZ = Range at which grazing angle was computed from PE spectral estimation.
!   RMD = Range mid-way between current and last PE range.
!   RSKIP = Approximate range interval of skip zone if duct is present.
!   RSQK = Height curvature offset: current output range squared divided by
!    (2*ek*a).

A.1.19 Subroutine RDTRACE

******************************************************************************
******************************************************************************

! Module Name: RDTRACE

! Module Security Classification: UNCLASSIFIED

! Purpose: Performs ray trace to determine grazing angles for subsequent
! use in rough surface calculations.

! Version Number: 1.3.0

! INPUTS:
! Argument List: THMXG
! Common: ANTREF, DR, FTER, HMAX, HTLIM, IHYBRID, IPE, ISTART1, PI2, RMAX, TWOKA
! Public: GRDUM(), HTDUM(), TYH()
! Parameter: PI
! Data: DEG10

! OUTPUTS:
! Argument List: IERROR
! Common: IGRZ
! Public: GRZ_RAY(),

! Modules Used: APM_MOD

! Calling Routines: GETGRAZE

! Routines Called:
! APM Specific: NONE
! Intrinsic: ALLOCATE, ALLOCATED, DABS, DATAN, DBLE, DEALLOCATE, DMOD, DSQRT, DTAN,
! MAX0, MIN0, SIGN

! GLOSSARY:

! Input Variables: See universal glossary for common and public variables.
! THMXG = Maximum PE propagation angle for grazing angle calcs (3 degrees).

! Output Variables: See universal glossary for common and public variables.
! IERROR = Integer flag returning error if one occurs.

! Local Variables:
! A0 = Angle at start of trace in radians.
! A1 = Angle at end of trace in radians.
! AIMC1 = Angle increment of 1e-3 degree.
A INC2 = Angle increment of 3e-3 degree.
A INC3 = Largest angle increment - approx.
AL = Launch angle
ANGMAX = Maximum angle to trace to.
DEGH = 1/2 degree in radians.
DEGT = 1.5 degrees in radians.
GRD = Gradient of current refractivity layer being traced through.
H0 = Height at start of trace in meters.
H1 = Height at end of trace in meters.
IHIT = Integer flag indicating if ray has hit surface:
  IHIT = 0 -> has not hit surface
  IHIT = 1 -> has hit surface
JL = Index for refractivity profile - current layer being traced through.
NMAX = Maximum number of grazing angles to store in GRZ_RAY(,)
NR1 = Number of rays to trace at increment of AINC1.
NR2 = Number of rays to trace at increment of AINC2.
NR3 = Number of rays to trace at increment of AINC3.
R0 = Range at start of trace in meters.
R1 = Range at end of trace in meters.
RSQK = Height offset to account for earth curvature.
TSLOPE = Slope of terrain segment at current traced range.
YNT = Height of terrain at current traced range.

A.1.23 Subroutine TRACE_ROUT

************************************************************************** SUBROUTINE TRACE_ROUT ************************************************

! Module Name: TRACE_ROUT

! Module Security Classification: UNCLASSIFIED

! Purpose: This routine traces a single ray to each output range ROUT and stores the height reached in array HARRAY.

! Version Number: 1.3.0

! INPUTS:
! Argument List: AS, GRDUM(), HS, HTDUM(), HTLIM, JLS, LVLEP, NROUT, RNGOUT(), RS
! Common: NONE
! Public: NONE

! OUTPUTS:
! Argument List: HARRAY(), IHMX
! Common: NONE
! Public: NONE

! Modules Used: NONE

! Calling Routines: FILLHT, GETTHMAX

! Routines Called:
! APM Specific: NONE
! Intrinsic: DABS, DMIN1, DSIGN, DSQRT, MIN0

! GLOSSARY:

! Input Variables:
! AS = Initial launch angle in radians
! GRDUM() = Array of refractivity gradients defined by profile HTDUM(), REFDUM()
! HS = Initial height in meters
! HTDUM() = Height array containing height values for current (interpolated) profile in meters, relative to HMINTER.
! HTLIM = user-supplied maximum height relative to HMINTER, i.e., HTLIM = HMAX - HMINTER
! JLS = Starting refractivity profile level
! LVLEP = Number of height/refractivity levels in profile REFDUM(),HTDUM() taken w.r.t. reference height HMINTER.
! NROUT = integer number of output range points desired
! RNGOUT() = array containing all output ranges in meters.
! RS = Initial range in meters

! Output Variables:
! HARRAY() = Height of ray at each output range.
! IHMX = Output range step index where maximum height HTLIM is reached in array HLIM().

! Local Variables:
! A0 = Angle at start of trace in radians.
! A1 = Angle at end of trace in radians.
! GRD = Gradient of current refractivity layer being traced through.
! H0 = Height at start of trace in meters.
! H1 = Height at end of trace in meters.
! IQUIT = Integer flag indicating when to terminate trace loop.
! JL = Index for refractivity profile - current layer being traced
! through.
! JR = Integer index counter.
! R0 = Range at start of trace in meters.
! RO = Current range to trace to.
! R1 = Range at end of trace in meters.

A.2.5 Subroutine FEM

! ************************** SUBROUTINE FEM *************************
!
! Module Name: FEM
!
! Module Security Classification: UNCLASSIFIED
!
! Purpose: This routine determines propagation loss based on flat 
!          earth calculations for all output heights specified at each 
!          output range ROUT.
!
! Version Number: 1.3.0
!
! INPUTS:
!     Argument List: ISTP, JFE, JFS, ROUT
!     Common: ANTREF, FRO, GASATT, HTLIM, PLCNST, TWOKA
!     Public: RSQRD(), ZOUTMA(), ZOUTPA()
!
! OUTPUTS:
!     Argument List: MPFL()
!     Common: ALPHAD
!
! Calling Routines: APMSTEP, XOSTEP
!
! Modules Used: APM_MOD
!
! Routines called:
!     APM Specific: ANTPAT, GETREFCOEF
!     Intrinsic: DATAN, DCOS, DLOG10, DMAX1, DSQRT, IIDNNT
!
! GLOSSARY: See universal glossary for common variables.
! ROUT = Current output range in meters.
! ISTP = Index of current output range step.

! Output Variables:
! JFE = Ending index within MPFL() of FE loss values.
! JFS = Starting index within MPFL() of FE loss values.
! MPFL(,) = 2-byte integer array containing propagation factor(F) and loss
! values in centibels vs. height, at each output range ROUT.
! All values returned are referenced to height HMIN.
! MPFL(1,i) = loss at output height i*DZOUT
! MPFL(2,i) = 20*log10(F) at output height i*DZOUT

! Local Variables:
! ALPHAR = Reflected ray angle.
! DLOSS = Propagation loss in dB.
! FACD = Antenna pattern factor for direct ray.
! FACR = Antenna pattern factor for reflected ray.
! FFAC2 = Square of pattern propagation factor.
! FFACDB = Pattern propagation factor squared in dB
! PHDIF = Total phase difference between direct and reflected ray,
! including phase change upon reflection.

A.2.15 Subroutine ROCALC

!******************** SUBROUTINE ROCALC *********************
Module Name: ROCALC

Module Security Classification: UNCLASSIFIED

PURPOSE: Computes and stores ray-optics components as needed to "span" range X. Arrays use the index K, where the elevation angle in radians at the origin is $\gamma = K/1000$. XROP and XRON are the ranges less and greater than X, respectively. IROP and IRON are indices of the component arrays that correspond to XROP and XRON. The arrays are: DMAGSQ(,) and RMAGSQ(,) - magnitude squared of the direct and reflected rays; and OMEGA(,) - phase angle in rad between direct and reflected rays. Ray-optics components are derived from calls to sub raytrace. Newton's method of iteration is used to find the direct and reflected elevation angles $\alpha_d$ and $\alpha_r$. Parallel-ray approximations are used as starting values for the highest value of K, otherwise the most recent values of $\alpha_d$ and $\alpha_r$ are used to start the iteration. Note that KMINP and KMINN are the minimum K values for good solutions at ranges XROP and XRON, and KMAX is the maximum K needed to exceed HTLIM at both XROP and XRON.

Version Number: 1.3.0 modified from RPO 1.15B

INPUTS:
- Argument List: X
- Common: ANTREF, BW, FKO, HTLIM, HTYDIF, IPOL, IRON, IROP, KMINN, PSILIM, TWOKA, XRON, XROP, YFREF, ZTOL
- Public: ZOUTMA(), ZOUTPA(), ZRO()
- Parameters: PI

OUTPUTS:
- Argument List: NONE
- Common: ALPHAD, DELXRO, DMAGSQ(,), HTYDIF, IRON, IROP, KMAX, KMINN, KMINP, OMEGA(,), RMAGSQ(,), XRON, XROP
- SAVE: DALPHA, FRACR0

Modules used: APM_MOD

CALLING ROUTINES: ROLOSS

ROUTINES CALLED:
- APM specific: ANTPAT, GETREFCOEF, RAYTRACE
- Intrinsic: COUNT, DABS, DATAN, DMAX1, IDINT

GLOSSARY: See universal glossary for common variables.

Input Variables:
- X = Current output range in meters
! Local Variables:
!   ALPHAR = reflected ray source elevation angle in radians
!   BETAD = direct ray terminal elevation angle in radians
!   BETAR = reflected ray terminal elevation angle in radians
!   DALPHA = one half the antenna beamwidth in radians
!   DXDAD = direct ray derivative of range w.r.t. elev angle
!   DXDAR = reflected ray derivative of range w.r.t. elev angle
!   DZDAD = direct ray derivative of height w.r.t. elev angle
!   DZDAR = reflected ray derivative of height w.r.t. elev angle
!   FRACRO = RO range step fraction (0. to .25)
!   FSQD = propagation factor squared for direct ray
!   FSQR = propagation factor squared for reflected ray
!   GMAXDA = term used in computing RO range step fraction
!   ITER = iteration counter (1 to 10)
!   ITYPE = ray type flag (0 = direct, 1 = reflected)
!   PFACD = antenna pattern factor for direct ray
!   PFACR = antenna pattern factor for reflected ray
!   PHI = phase lag of reflection coefficient in radians
!   PLDD = path length difference from x for direct ray
!   PLDR = path length difference from x for reflected ray
!   PSI = grazing angle in radians
!   REFCOEFF = complex reflection coefficient
!   RMAG = magnitude of reflection coefficient
!   XREFLECT = Range at which ray is reflected in RO and FE calculations.
!   ZD = terminal height of direct ray in meters
!   ZK = height of kth RO index in meters
!   ZR = terminal height of reflected ray in meters

!Module Name: ROLOSS

!Module Security Classification: UNCLASSIFIED

PURPOSE: Sets propagation loss in centibels at range ROUT for j from
JMAX to JMIN based on 3 arrays obtained from sub ROCALC: DMAGSQ(,),
RMAGSQ(,), and OMEGA(,). The 3 arrays are stored in order of (i,k),
where i = 1 indicates components at range XROP (<ROUTE), and i = 1
indicates components at range XRON (>ROUTE). K is the origin ray
angle integer index in mrad [i.e. 1000 * angle]. KMINP and KMINN
are the minimum good values of K at XROP and XRON, and KMAX is the
maximum value of K where good components are stored at both XROP
and XRON.

Version Number: 1.3.0 modified from RPO 1.15B

INPUTS:
Argument list: ISTP, JMAX, JMIN, ROUT
Common: DELXRO, DMAGSQ(,), GASLOSS, IRON, IROP, KMAX, KMINN, KMINP, OMEGA(,),
RMAGSQ(,), XROP
Public: FSL(,), ZRO()

OUTPUTS:
Argument list: MPFL(,)
Common: NONE

SAVE: DANGHI, DANGLO, DFSDHI, DFSDLO, DFSRHI, DFSRLO

Modules Used: APM_MOD

CALLING ROUTINES: APMSTEP, XOSTEP

ROUTINES CALLED:
APM Specific: ROCALC
Intrinsic: DABS, DCOS, DLOG10, DMAX1, DSQRT, IDINT, IIDNNT

GLOSSARY: See universal glossary for common variables.

Input Variables:
ISTP - Current output range step index.
JMAX - Ending index within MPFL(,) of RO loss values.
JMIN - Starting index within MPFL(,) of RO loss values.
ROUTE - Current output range in meters.

Output Variables:
```
MPFL(,) = 2-byte integer array containing propagation factor (F) and loss values in centibels vs. height, at each output range ROUT.
All values returned are referenced to height HMIN.
MPFL(1,i) = loss at output height equal to i*DZOUT
MPFL(2,i) = 20*log10(F) at output height equal to i*DZOUT

Local Variables:
ANG = phase angle for computing FSQ in radians
ANGHI = phase angle above desired point in radians
ANGLO = phase angle below desired point in radians
DANGHI = diff. in phase angle along RO step above desired point
DANGLO = diff. in phase angle along RO step below desired point
DFSDHI = diff. in dir. mag**2 along RO step above desired point
DFSDLO = diff. in dir. mag**2 along RO step below desired point
DFSRHI = diff. in ref. mag**2 along RO step above desired point
DFSRLO = diff. in ref. mag**2 along RO step below desired point
FK = floating value of K index at jth output point
FFAC = propagation factor in dB
FSDHI = direct ray magnitude squared above desired point
FSDLO = direct ray magnitude squared below desired point
FSQ = propagation factor squared at desired point
FSQR = reflected ray magnitude squared at desired point
FSRH = reflected ray magnitude squared above desired point
FSRLO = reflected ray magnitude squared below desired point
KHI = K index above desired point
KLO = K index below desired point
KLOTMP = temporary KLO value
RATIOK = fraction of one K index (0. to 1.)
RATIOX = fraction of current RO range step (0. to 1.)

! Calling Routines: CALLOS, EXTO

! Routines Called:
! APM Specific: ANTPAT
! Intrinsic: AMAX0, DBLE, DEXP, DLOG10, DMAX1, DMIN1, MINLOC

! GLOSSARY:

! Input Variables:
! ISTP = Current output range step index.
! JS = Starting index in ZOUT() for troposcatter calculations.
! JE = Ending index in ZOUT() for troposcatter calculations.
! RLOSS() = Propagation loss in dB vs. height at range ROUT.

! Output Variables
! RLOSS() = Propagation/troposcatter loss in dB vs. height at range ROUT.

! Local Variables:
! A1MIN = 1-element array containing subscript of minimum value
! in TH() array.
! AL = Angle defined by equ. 115 in EREPS 3.0 User's Manual
! NRAg TD 2648, pp. 105.
! ALD = Log of antenna pattern factor for ALPHAD where ALPHAD here
represents lowest direct ray angle in optical region.

BE = Angle defined in eq. 116 in EREPS 3.0 User's Manual
NRAD TD 2648, pp. 105.

BIGH = Frequency gain function defined in eq. 119 in EREPS 3.0 User's Manual
NRAD TD 2648, pp. 106.

CT1 = Quantity defined in eq. 124 in EREPS 3.0 User's Manual
NRAD TD 2648, pp. 106.

CT2 = Quantity defined in eq. 125 in EREPS 3.0 User's Manual
NRAD TD 2648, pp. 106.

D1 = Range from source to tangent point in meters.
D2 = Range from receiver to tangent point in meters.

DELHO = Frequency gain function correction term defined in eq.

ER = Exponent used in troposcatter calcs = -4/3

ETAS = Quantity defined in eq. 126 in EREPS 3.0 User's Manual
NRAD TD 2648, pp. 106.

H0 = Effective scattering height - defined in eq. 109 in

HOR1 = Quantity defined in eq. 120 in EREPS 3.0 User's Manual
NRAD TD 2648, pp. 106.

HOR2 = Quantity defined in eq. 121 in EREPS 3.0 User's Manual
NRAD TD 2648, pp. 106.

JT1 = Index counter for TH1() array.
JZ = Current output height index.

QT = Quantity defined in eq. 128 in EREPS 3.0 User's Manual
NRAD TD 2648, pp. 107.

R1 = Quantity defined in eq. 122 in EREPS 3.0 User's Manual
NRAD TD 2648, pp. 106.

R2 = Quantity defined in eq. 123 in EREPS 3.0 User's Manual

A.5 MODULE APM_MOD

module apm_mod
    real( kind=8 ) pi
    parameter ( pi = 3.1415926535897932d0 ) !Self-explanatory
    parameter ( irtemp = 200 ) !Number of range steps for use in ray-tracing
! to determine maximum PE angle.

! ERRORFLAG:
! LERR6 = Logical flag that allows for greater flexibility in allowing error
! -6 to be bypassed. If set to .TRUE. then trapping for this error
! occurs, otherwise it can be totally ignored by main driver program.
! (Within the APM program it is handled as a warning). If this
! error is bypassed (LERR6 = .FALSE.) terrain profile is extended to
! RMAX with same elevation height of last valid terrain profile point.
! LERR12 = Same as LERR6 - allows for trapping of this error. If LERR12 =
! .FALSE., then (for range-dependent case) if range of last
! refractivity profile entered is less than RMAX, the environment
! is treated as homogeneous from the last profile entered to RMAX.

common / errorflag / lerr6, lerr12
logical( kind=2 ) lerr6, lerr12

! INPUTVAR:
! HMAX = Maximum output height with respect to m.s.l. in meters. If PEFLAG=.FALSE.
! then HMAX must be at least 100 m.
! HMIN = Minimum output height with respect to m.s.l. in meters. If PEFLAG=.FALSE.
! then HMIN must be specified such that HMAX-HMIN is at least 100 m.
! NZOUT = Integer number of output height points desired
! NROUT = Integer number of output range points desired
! PEFLAG = Logical flag indicating if pure PE model will be used.
! *CAUTION*: Setting this flag overrides most error checks and limits.
! PEFLAG = .TRUE. -> perform entire run using only PE model
! PEFLAG = .FALSE. -> use normal hybrid models as appropriate
! RMAX = Maximum output range in meters. If PEFLAG=.FALSE. then RMAX must be at
! least 5 km.
! RMULT = PE range-step multiplier. Multiplies the internally-computed PE
! range step by the factor RMULT. This must be specified if
! PEFLAG=.TRUE. and a greater or lower value for the automatically-
! calculated range step is desired. Default value is 1.
! THMAX = Maximum calculation PE propagation angle in degrees. This must be
! specified if PEFLAG=.TRUE. Otherwise this value is ignored.
! TROPO = Logical flag indicating if troposcatter calculations are
! to be performed:
! TROPO = .FALSE. -> no troposcatter calculations
! TROPO = .TRUE. -> perform troposcatter calculations

common / inputvar / hmax, hmin, rmax, rmult, thmax, nzout, nrout, peflag, tropo
real( kind=8 ) hmax, hmin, rmax, rmult, thmax
integer( kind=4 ) nzout, nrout
logical( kind=4 ) peflag, tropo

! REFRACTIVITY common block and associated input variables:
! ABSHUM = Absolute humidity near the surface in g/m3.
! GAMMMA = Gaseous absorption in dB/km.
! HMSL(,)= Dynamically allocated 2-dimensional array of size
! (0:LVLP,NPROF) containing heights in meters with respect
! to mean sea level of each profile. Array format must be
! HMSL(I,J) = height of Ith level of Jth profile. J = 1
! for range-independent cases.
! ********************************** NOTE: ******************************
! LVLP is the actual # of height levels occupying 0 to LVLP-1
! elements in array HMSL; there will be an extra point
! unused on input.
! ************************************************************

! IEXTRA = Extrapolation flag for refractivity profiles entered in combination
! with terrain below m.s.l.
! IEXTRA = 0 -> extrapolate to minimum terrain height using
! standard atmosphere gradient.
! IEXTRA = 1 -> extrapolate to minimum terrain height using
! HMAX with same gradient in profile. First level in profile
! LVLP = Number of levels in refractivity profile (for range dependent
! case all profiles must have same number of levels).
! NPROF = Number of profiles - equals 1 for range-independent cases.
NW - Number of wind speeds and corresponding ranges.

REFMSL(,) = Dynamically allocated 2-dimensional array of size
(0:LVLP,NPROF) containing refractivity with respect to
mean sea level of each profile. Array format must be
REFMSL(I,J) = M-unit value at Ith level of Jth profile.
J = 1 for range-independent cases.

************************** NOTE: **************************
LVLP is the actual # of refractivity levels occupying 0 to
LVLP-1 elements in array REFMSL; there will be an extra
point unused on input.

************************** NOTE: **************************
RNGPROF() - Ranges of each profile in meters, i.e., RNGPROF(I) = range of
Ith profile. RNGPROF(I) should always be equal to 0.
RNGWIND() - Ranges in meters, for each wind speed specified in WIND;
i.e., RNGWIND(1) should always be equal to 0.
TAIR - Air temperature near the surface in degrees C.
WIND() - Dynamically allocated array containing wind speeds in
meters/second. Must also specify corresponding ranges in
RNGWIND(). Wind speeds must be no greater than 10 m/s.

For Compaq Visual Fortran Ver. 6.6 Fortran 95 compilation using
dynamically allocated arrays, the following source code MUST be in the
main driver (calling) program before initialization of the arrays can
be performed:

! IF( ALLOCATED( HMSL ) ) DEALLOCATE( HMSL )
! ALLOCATE( HMLS(0:LVLP, NPROF) )
! HMLS = 0.

! IF( ALLOCATED( REFMSL ) ) DEALLOCATE( REFMSL )
! ALLOCATE( REFMSL(0:LVLP, NPROF) )
! REFMSL = 0.

! IF( ALLOCATED( RNGPROF ) ) DEALLOCATE( RNGPROF )
! ALLOCATE( RNGPROF(NPROF) )
! RNGPROF = 0.

! IF( ALLOCATED( RNGWIND ) ) DEALLOCATE( RNGWIND )
! ALLOCATE( RNGWIND(NW) )
! RNGWIND = 0.

! IF( ALLOCATED( WIND ) ) DEALLOCATE( WIND )
! ALLOCATE( WIND(NW) )
! WIND = 0.

Once the above source code has been inserted in the main (calling)
routine, the arrays can then be initialized with the desired refrac-
tivity profiles for subsequent use by routines APMiniT and APmSTEp.
angles corresponding to antenna pattern factors (IPAT=7). Angles must be specified in increasing order from lowest to highest. This is only used for antenna type 6 and 7.

HFFAC() = Dynamically allocated array of power cut-back factors (IPAT=6) or antenna pattern factors (IPAT=7). This is only used for antenna type 6 and 7.

IPAT = Integer value indicating type of antenna pattern desired
- IPAT = 1 -> omni
- IPAT = 2 -> gaussian
- IPAT = 3 -> sinc x
- IPAT = 4 -> csc**2 x
- IPAT = 5 -> generic height-finder
- IPAT = 6 -> user-defined height-finder (must specify power reduction factors and corresponding angles in arrays HFFAC(), HFANG() )
- IPAT = 7 -> user-defined antenna pattern (must specify antenna pattern factors and corresponding angles in arrays HFFAC(), HFANG() )

IPOL = integer indicating polarization.
- IPOL = 0 -> horizontal
- IPOL = 1 -> vertical

NFACS = Number of user-defined cut-back angles and cut-back antenna pattern factors for user-defined height-finder antenna type.

************************************************************************
For Compaq Visual Fortran Ver. 6.6 Fortran 95 compilation using dynamically allocated arrays, the following source code MUST be in the main driver (calling) program before initialization of the arrays can be performed:

```
IF( ALLOCATED( HFANG ) ) DEALLOCATE( HFANG )
ALLOCATE( HFANG(NFACS) )
HFANG = 0.

IF( ALLOCATED( HFFAC ) ) DEALLOCATE( HFFAC )
ALLOCATE( HFFAC(NFACS) )
HFFAC = 0.
```

Once the above source code has been inserted in the main (calling) routine, the arrays can then be initialized with the desired cut-back angles and factors for subsequent use by routines APMINIT and APMSTEP.

public :: hfang, hffac

TERRAIN common block and associated input variables:
- DIELEC(, ) = Dynamically allocated 2-dimensional array of size (2,IGR) containing the relative permittivity and conductivity; DIELEC(1,i) and DIELEC(2,i), respectively. Only needs to be specified if using IGRND(i) = 7, otherwise, APM will calculate based on frequency and ground types 0-6.
- IGR = number of different ground types specified
- IGRND() = Dynamically allocated integer array of size IGR containing ground type composition for given terrain profile - can vary with range. Different ground types are:
  - 0 = sea water
  - 1 = fresh water
  - 2 = wet ground
  - 3 = medium dry ground
  - 4 = very dry ground
  - 5 = ice at -1 degree C
  - 6 = ice at -10 degree C
  - 7 = user defined (in which case, values of relative permittivity and conductivity in S/m must be given).
! ITP = number of height/range pairs in profile
! RGRND() = Dynamically allocated array of size (IGR) containing ranges,
! in m, at which the ground types apply.
! TERX() = Dynamically allocated array of size (ITP) containing range
! points of terrain profile in meters.
! TERY() = Dynamically allocated array of size (ITP) containing height
! points of terrain profile in meters.

! Common Block APM_VAR

! AATZ = Local propagation angle in radians at height ZLIM and range RATZ
! (used for hybrid modes).
! ACRIT = Critical angle (angle above which no rays are trapped)
! in radians.
! ACUT = Tangent angle in radians from antenna height to horizon range.
! AEK = Mean earth radius times the effective earth radius factor EK.
! AFAC = Constant used in determining antenna pattern factors
! AFAC = 1.39157 / sin( bw / 2 ) for SIN(X)/X and height-finder
! AFAC = (.5*ln(2))/((sin(bw/2))**2 for GAUSSIAN
! A LAUNCH = Launch angle used, in radians, which, when traced, separates
! PE & XO regions from RO region
! ALPHAD = Direct ray elevation angle in radians
! ALPHAQ = Complex surface impedance.
! ANTREF = Transmitting antenna height relative to the reference
! height HMINTER.
! BW = Antenna pattern beamwidth in radians.
! C1X = Constant dependent on each new calculated RT - used to
! calculate CK1 at next range step.
! C2X = Constant dependent on each new calculated RT - used to
! calculate CK2 at next range step.
CK1 = Coefficients used in old central difference DMFT calculations.
CK2 = Coefficients used in old central difference DMFT calculations.
CMFT = Coefficient used in backward difference DMFT calculations.
CMFT_X = Constant dependent on each new calculated RT - used to
calculate CMFT at next range step.
CON = 1.e-6 * FKO; Constant used in calculation of ENVPR().
DELP = Mesh size in angle- (or p-) space.
DELXRO = RO range increment in meters
DELZ = Bin width in z-space = WL / (2*sin(THETAMAX))
DMAGSQ(,) = direct-ray magnitude squared - used in RO calculations.
DR = PE range step in meters
DR2 = 1/2 PE range step in meters
DRGRZ = Range step in meters used in estimating grazing angles.
DROUT = Output range step in meters
DTETA = Angle bin width (i.e., incremental sine(theta))
DZ2 = 2. * DELZ
DZOUT = Output height increment in meters
EK = Effective earth radius factor.
ELV = Antenna pattern elevation angle in radians
FKO = Free-space wavenumber = (2*pi) / WL
FKO2 = 2. * FKO
FNORM = Normalization factor used for DFT.
FTER = logical flag - .TRUE. = terrain case, .FALSE. = over-water case
GASATT = Gaseous absorption in dB/m.
GASLOSS = Gaseous absorption loss in dB.
HMINTER = Minimum height of terrain profile in meters. This will be
used to adjust entire terrain profile so all internal
calculations will be referenced to this height.
HMREF = Height relative to HMINTER. Determined from user-provided
minimum height HMIN. That is, if HMIN is minimum height input
by user with respect to mean sea level, and HMINTER is
internally considered the new origin, then HMREF = HMIN - HMINTER.
HTEMP() = Heights at which ray is traced to every range point RTEMP(i)
HTLIM = User-supplied maximum height relative to HMINTER, i.e.,
HTLIM = HMAX - HMINTER
HTYDIF = Height difference between internal maximum height, HTLIM,
and initial ground height at the source, YFREF.
IALG = Index indicating which DMFT algorithm is being used:
   0 = no DMFT being used
   1 = old central difference algorithm
   2 = backward difference algorithm
IAP = Index indicating when local ray angle becomes positive in array
       RAYA().
IG = Counter indicating current ground type being modeled.
IGPE = Number of grazing angles computed from spectral estimation.
IGRZ = Number of grazing angles computed from ray trace and total # of
       grazing angles.
IHMX = Output range step index where maximum height HTLIM is reached in
       array HLIM().
IHYBRID = Integer indicating which sub-models will be used:
   0 = airborne hybrid (FE+PE) model
   1 = full hybrid (FE+RO+PE+XO) model
   2 = PE + XO model
IO = Starting index for MFPL array:
   IO=0 -> 1st calculated point is at surface (0.0 height)
   IO=1 -> 1st calculated point is at height DZOUT
IPE = Number of PE range steps.
IRATZ = Index of output range step at which ZLIM is reached (for
        hybrid model only). Indicates at what range step begin
        storing propagation factor and outgoing angle for XO region.
IRON = Next index for RO solution (0 or 1)
IROP = Previous index for RO solution (-1, 0, or 1)
IS = Counter for current profile (for range-dependent cases)
ISM2 = 1/2 of data variable ISM
ISTART = RO height index at transmitter.
ISTART1 = Refractivity level index within HTDUM() at transmitter.
ITPA = Number of terrain points used internally in arrays TX() and TY().
IXO = Number of range steps in XO calculation region.
IZ = Counter for points stored in FFAST(,). array
IZG = Output height integer index indicating the last height representing
      terrain.
IZINC = Integer increment for storing points at top of PE region to start XO model. I.e., points are stored at every IZINC range step.
IZMAX = Maximum # of points allocated for arrays associated with XO calcs.
JT2 = Index counter for TYH() array indicating where range is at each terrain inflection, i.e., "range at TYH(JT2-1)" < ROUT < "range at TYH(JT2)".
JZLIM = PE bin # corresponding to ZLIM, i.e., ZLIM = JZLIM*DELZ.
KMAX = Maximum K-index at XROP and XRON
KMINN = Minimum K-index at XRON
KMINP = Minimum K-index at XROP
KTR1 = Number of increasing tangent angles and ranges determined from source height over terrain path profile.
LDUCT = Logical flag indicating if surface-based duct profile has been specified:
      .FALSE. - no duct
      .TRUE. - duct
LEVAP = Logical flag indicating if evaporation duct refractivity profile has been specified:
      .FALSE. - no evaporation duct
      .TRUE. - evaporation duct
LEVELS = number of levels defined in ZRT(), Q(), and GR() arrays
LN = Power of 2 transform size, i.e. N = 2**LN
LNMP = Minimum power of 2 transform size.
LNP = Power of 2 transform size used in spectral estimation calcs.
LVLEP = Number of height/refractivity levels in profile REFDUM(),HTDUM(), taken w.r.t. reference height HMINTER.
N = Transform size
N34 = 3/4 * N
NF4 = N / 4
NLVL = Number of height/refractivity levels in profile REREF(),HREF(), taken w.r.t. local ground height at middle of range step, YCURM.
NMI = N-1
NOPE = Integer flag indicating if PE calcs are needed:
      0 = PE calcs are needed.
      1 = PE calcs are not needed.
NP34 = 3/4 * NPNTS
NP4 = NPNTS / 4
NPNTS = Number of points used in top part of PE region for spectral estimation.
NS = Transform size used in spectral estimation calcs = 2**N
NSM1 = NS - 1
OMEGA(,) = Phase angle between direct & reflected rays in radians - used in RO calculations.
PELEV = Sine of elevation angle
PLCNST = Constant used in determining propagation loss
      PLCNST = 20log(2*FKO).
PSILIM = Grazing angle of limiting ray in radians
QIFKO = Imaginary i * FKO
R1T = Constant used in troposcatter calcs. = RF*ANTREF
RATZ = Range at which ZLIM is reached (used for hybrid model).
RAYA() = Array containing all local angles of traced ray ALAUNCH at each output range.
RF = Constant used in troposcatter calcs. = 4*PI*FREQ/speed of light (x10e6)
RHOR = Radar horizon range in meters for 0 receiver height.
RK = Constant used in central difference DMFT.
RLOG = 10. * alog10( PE range )
RLOGLST = RLOG of previous range step (i.e., 10*alog10(PE range-DR) )
RMAGSQ(,) = Reflected-ray magnitude squared - used in RO calculations
RMTX = M-unit value * 1.e-6 at transmitter
RPEST = Range in meters at which loss values from the PE model will start being calculated.
RT = Complex root for mixed transform method based on Kuttler's formulation.
RTEMP() = Range steps for tracing to determine maximum PE angle.
RUF = Logical flag indicating if performing a rough sea surface calculation:
      .FALSE. - smooth sea surface; 0 wind speed
      .TRUE. - rough sea surface; use wind speeds specified in array WIND()
RUF_FAC = Factor used for wave height calculation.
RUF_HT = Sea surface wave height.
RV2 = Range of the next refractivity profile (for range-dependent cases)
SBW = Sine of the beamwidth.
SNREF_TX = Surface refractivity at source.
TERANG = Current maximum angle made by tangent line from transmitting antenna height to all terrain elevation points up to the current output range. (Used only for IHYBRID=0)

THETA1S = Tangent angle from source for smooth surface.

THETA75 = 75% of maximum propagation angle in PE calculations.

TLSTWR = Troposcatter loss term for smooth surface (non-terrain), before addition of surface refractivity term.

TWOKA = Twice the effective earth's radius factor times the effective earth radius. The effective earth's radius factor is calculated based on a ray trace at 5 degrees from the origin to HTLIM for IHYBRID=1 and from the antenna height to HTLIM for IHYBRID =0. This is used for routine FEM.

TWOKA_DOWN = Twice the effective earth's radius factor times the effective earth radius. The effective earth's radius factor is calculated based on a ray trace at -5 degrees from the antenna to the surface. This is used for routine AIRBORNE.

UMAX = limiting angle used in cut-off point for SIN(X)/X and generic height-finder antenna pattern factors

WL = Wavelength in meters.

XILIMRO = range of limiting ray in meters

XOCON = Constant used in determining outgoing propagation angle for XO calcs -> WL / (2*NS*DELZ).

XRON = next range for RO solution in meters

XROP = previous range for RO solution in meters

YCUR = height of ground at the current range step

YCURM = height of ground midway between last and current range step. For use when shifting profiles to be relative to the local ground height.

YFREF = Ground elevation height at source.

YLAST = height of ground at the last range step

ZLIM = Maximum internal height (HTLIM) or .75*ZMAX, whichever is smaller.

ZMAX = Maximum height of PE calculation domain = N * DELZ

ZTOL = height tolerance for Newton's method in meters

common / apm_var / htemp(irtemp), raya(irtemp), rtemp(irtemp), dmagsq(0:1,0:88), omega(0:1,0:88), rmagsq(0:1,0:88), alphaq, c1x, c2x, ck1, ck2, cmft, cmft_x, qifko, rk, rt, aatz, acrit, acut, aek, afac, alaunch, alimv, alphad, antref, bw, con, delp, delxRO, delz, dr, dr2, drgrz, drou, dtheta, dz2, dzout, ek, elv, fko, fko2, fnorm, gasatt, gasloss, hminter, hmref, htlim, htydif, pelev, pi2, plcnst, psilm, r1t, ratz, rf, rhor, rlog, rloglst, rmtx, rpest, ruf_fac, ruf ht, rv2, sbw, snref tx, terang, theta75, tlstwr, twoka, twoka_down, umax, umax3, wi, xilimRO, xocon, xROn, ycur, ycurm, yfref, ylast, zlim, zmax, ztol, & iaig, iap, ig, igpe, igrz, ihmx, ihybrid, io, ipe, iratz, iROn, & iROp, is, ism2, istart, istartl, itpa, ixo, iz, izg, izinc, & imax, jtz2, jzlim, kmax, kminn, kminp, ktr1, levels, ln, lnmin, & lnp, lvlep, n, n34, nf4, nlvl, nml, nope, np34, np4, npnts, ns, & nml, fter, lduct, levap, ruf

************************************************************************ DYNAMICALLY ALLOCATED ARRAYS ************************************************************************
ADIF() - Height array in meters used for troposcatter calcs.

CNZ() - Complex dielectric constant.

CURANG() - Current local angle for each ray being traced in XO region.

CURHT() - Current local height for each ray being traced in XO region.

CURNG() - Current local range for each ray being traced in XO region.

D2S() - Tangent range array in meters for all output receiver heights.  

over smooth surface.

ENVPR() - Complex array containing refractivity exponential term.  

i.e. ENVPR() = exp[i * DR * FKO * \(1 \times 10^{-6} \times M(z)\)], where  

M(z) is the refractivity at each PE bin height z.

FFACZ(,) - 2-dimensional array containing propagation factor in dB,  

range, and propagation angle at ZLIM.  Used to start XO  

calculations.

FFACZ(IZ,1) = propagation factor in dB at current PE range

FFACZ(IZ,2) = current PE range

FFACZ(IZ,3) = propagation angle at current PE range at ZLIM

FFRINT() = Propagation factor in dB at each output range step  

beyond RATZ and at height ZLIM

FILT() = Cosine-tapered (Tukey) filter array.

FILTP() = Array filter for spectral estimation calcs.

FRSP() = Complex array containing wide-angle free-space propagator exponential  

term; i.e., FRSP() = exp[-i * DR * (FKO - sqrt(FKO^2 - p^2))]

FSL() = Array containing the free space loss at every output range.

GR() = 1.E-6 * \(dM/dz\) array used for RO calculations

GRAD(,) = 2-dimensional array containing gradients of each refrac-

tivity profile vs. range from height ZLIM to HTLIM.

GRAZE() = Array of final interpolated grazing angles determined for rough  

surface calculations.

GRDUM() = Array of refractivity gradients defined by profile HTDUM(), REFDUM()  

GRZ_PE() = Grazing angles computed from spectral estimation.

GRZ_RAY() = Grazing angles computed from ray trace

HFANGR() = Array of user-defined cut-back angles (IPAT=6) or antenna pattern  

factor angles (IPAT=7) in radians.  This is  

used only for antenna types 6 and 7.

HLIM() = Array containing height at each output range separating the  

RO region from the PE (at close ranges) and XO (at farther  

ranges) regions

HREF() = Heights of refractivity profile with respect to YREF (local  

ground height).

HT() = Height array of size N.  Heights space every DELZ.

HTDUM() = Height array containing height values for current (interpolated)  

profile in meters, relative to HMINTER.

HTFE() = Array containing the height at each output range step separa-

ting the flat earth region from the RO region.

HTR(,) = 2-dimensional array containing height levels of each refrac-

tivity profile vs. range from height ZLIM to HTLIM.

IGRD() = Integer indexes indicating at what gradient in GRAD(,) to  

begin raytracing for next XO range step for each ray in XO  

region.

LVL() = Number of refractivity levels in current refractivity profile  

from ZLIM to HTLIM.

PRFH_XO(,) = Propagation factor and height for each ray traced in XO region  

at range ROUT.

PROFINT() = M-unit profile interpolated to every DELZ in height  

Q() = 2 * [RM(i+1)-RM(i)] array used for RO calculations

RDT() = Minimum range array (in meters) at which diffraction field  

solutions are applicable and intermediate region ends (for  

smooth surface) for all output receiver heights.

REFDUM() = Dummy array containing M-unit values for current (interpolated)  

profile taken relative to HMINTER.

REFREF() = Refractivity array w.r.t. YREF (local ground height).

RFAC1() = Propagation factor at valid output height points computed  

from PE field at previous PE range, i.e., ULST().

RFAC2() = Propagation factor at valid output height points computed  

from PE field at current PE range, i.e., U().

RLOGO() = Array of logarithm of output ranges, i.e., RLOGO(i) =  

20. * ALOG10(i*DROUT).

RLOSS() = Propagation loss in dB.

RM() = 1.E-6 * M array used for RO calculations.

RN() = Array of RT to the i'th power, i.e. RN(I) = RT**I
RNGOUT() = Array containing all output ranges in meters.
RSQRD() = Double precision array containing the square of output ranges
SLP() = Slope of each segment of terrain.
SPECTR() = Field amplitude of spectral portion of PE field in dB.
TH1() = Tangent angles from source height w/ terrain path profile.
THETA0() = Angle array - angles used in determining common volume scattering angle.
THETA2S() = Tangent angle array from all output receiver heights for smooth surface.
TX() = Range points of terrain profile in meters.
TY() = Adjusted height points of terrain profile in meters.
TYH() = Adjusted height points of terrain profile at every PE range step.
U() = Complex array containing PE field solution.
UDUM() = Dummy array used for temporary storage of real or imaginary part of complex PE field array U().
ULST() = Complex array containing PE field solution at previous range step.
W() = Difference equation of complex PE field array. Used in intermediate calculations only for vertical polarization.
XP() = Real part of spectral portion of PE field.
YM() = Field from recursion equation for central difference DMFT.
YP() = Imaginary part of spectral portion of PE field.
ZOUT() = Array containing all output heights in meters referenced to HMINTER.
ZOUTMA() = Array containing output heights in meters relative to the antenna height above ground at 0 range. Used in FE model.
ZOUTPA() = Array containing output heights in meters relative to the image antenna height below ground at 0 range. Used in FE model.
ZRO() = Output height array in meters referenced to ground elevation height at source. Used for RO calculations.
ZRT() = Height array used for RO calculations in meters

1. SCOPE

1.1 IDENTIFICATION

The Advanced Propagation Model (APM) Version 1.3.1 computer software configuration item (CSCI) calculates range-dependent electromagnetic (EM) system propagation loss and propagation factor within a heterogeneous atmospheric medium over variable terrain, where the radio-frequency index of refraction is allowed to vary both vertically and horizontally. Numerous Naval Integrated Tactical Environmental Subsystem (NITES) applications require EM-system propagation loss values. The APM model described by this document may be applied to two such NITES applications, one which displays propagation loss on a range versus height scale (commonly referred to as a coverage diagram) and one which displays propagation loss on a propagation loss versus range/height scale (commonly referred to as a loss diagram).

1.2 DOCUMENT OVERVIEW

This document specifies the test cases and test procedures necessary to perform qualification testing of the APM CSCI. A discussion of precise input values of each input variable required to perform the test together with final expected test results is presented.

2. REFERENCE DOCUMENTS

3. TEST PREPARATIONS

3.1 HARDWARE PREPARATION

Not applicable

3.2 SOFTWARE PREPARATION

A short driver program, APMMAIN.F90, is provided in Section 7. This program exercises the main software components, APMINIT CSC, APMSTEP CSC, XOINIT CSC, and XOSTEP CSC that comprise the APM CSCI. The driver program demonstrates how to access the APM CSCI and to exercise the test cases listed in the following sections. It is written to read all necessary input data for the test cases from files in a specific format. All necessary input information is presented in tabular form in Section 4.3 and the input files for each test case are listed in Section 8.

One of the main features of APM is the use of dynamic allocation in most of the arrays used for both numeric calculations and as inputs to the model. Care must be taken by the NITES CSCI application designer to properly allocate memory and initialize all variable and array inputs to APM. Ultimately, it is the responsibility of the NITES CSCI application designer to provide the necessary input in the form required by the APM CSCI.

3.3 OTHER PRETEST PREPARATION

None.
4. TEST DESCRIPTIONS

The test specification for the APM CSCI consists of 36 separate tests that exercise all subroutines and functions of the CSCI. For ease of testing, each of these 36 tests is given a name describing which portion of the APM CSCI is being exercised. All 36 tests and their descriptions are listed in Table 1.

4.1 REQUIREMENTS ADDRESSED

Not applicable.

4.2 PREREQUISITE CONDITIONS

None.

4.3 TEST INPUTS

Although there are actual values for all input parameters listed in the input files in Section 8, some are ignored depending on the values of certain input parameters. Those input parameters that are inapplicable depending on the test case are listed as “N/A” in the tables. Note that for all test cases, the error flags _lerr6_ and _lerr12_ are set to “.TRUE.”. These flags allow for extra error control regarding terrain and refractivity inputs. We recommend that these error flags always be set to “.TRUE.”. However, we allowed the capability of the NITES applications designer to bypass these error controls according to the application.

The external environmental data element requirements are listed in Table 2 for each test name, with Table 3 through Table 8 providing specific height and M-unit values. The external EM system data element requirements are listed Table 9.

</tbody>
</table>
4.5 CRITERIA FOR EVALUATING RESULTS

The calculated propagation loss in dB should match the numerical values in each table at each of the levels shown to within 0.1 dB (1 cB). APM rounds its output loss values to the nearest 1 cB, and hence it is possible for differences of 1 cB to exist between different implementations of APM. It is expected, however, that in most cases the values will match those in Table 24 through Table 59 exactly.

4.6 TEST PROCEDURE

1. Compile for execution, the APM CSCI, the driver program APMMMAIN.F90, and the module APM_MOD.F90.

2. An input data file has been provided, as a text file, for each test case.

3. The APM CSCI is executed in a form that reads the input data file, performs the calculations, and writes the output to a text file.

4. The output file is compared to the final expected test results to determine satisfactory performance.

4.7 ASSUMPTIONS AND CONSTRAINTS

Input data elements are assumed to be constrained by the limits listed within Tables 1 through 4 of the Software Requirements Specification (Ref. 5).

5. REQUIREMENTS TRACEABILITY

The provided driver program that accesses the APM CSCI will create an output file for each test case. The output file will have the same prefix name as the input file. The extension is “.OUT”. This output file contains height in meters and corresponding propagation loss in dB that should correspond to the entries in Table 24 through Table 59 for each test case.

The provided program APMMMAIN.FOR, when compiled with the APM CSCI, will read the provided input files containing all necessary information for each test case. Each input file is named for each test case, with a “.IN” extension.

7. SAMPLE PROGRAM LISTING

The sample driver program APMMAIN.FOR, which exercises the APM CSCI, is provided below.

!******************* APMMAIN DRIVER PROGRAM FOR APM Ver 1.3.1 ********************
! This is a sample driver program for APM routines APMINIT, APMSTEP,
! XOINIT, and XOSTEP. All numeric parameters passed to APMINIT and
! APMSTEP must be in metric units. All input arrays are dynamically
! allocated and are dimensioned with variable sizes.

program apmmain
use apm_mod
implicit integer(kind=4) (i-n)
implicit real(kind=8) (a-h, o-z)
!MPFL must be declared an INTEGER*2 allocatable array.
!ITLOSS is a dummy array and will be used to store entire loss grid.
!ITPFAC is a dummy array and will be used to store entire propagation factor grid.
!NOTE: Propagation factor is output as 20*LOG10(F).
integer(kind=2), allocatable :: mpfl(:,,:), itloss(:,,:), itpfac(:,,:)
character filein*20, fileout*24, answer*1
10 continue
write(*,'(a)')' Name of input file? '
read(*, '(a)') filein

8. INPUT FILE LISTINGS FOR TEST CASES

Each test case, when using the sample driver program APMMAIN.F90, shall consist of an input file (TestName.IN) and an output file (TestName.OUT). The input file’s contents are listed in sections 8.1 through 8.28. The output file’s contents, consisting of couplets of height in meters and propagation loss and propagation factor in dB, are listed in Table 24 through Table 59.

**ADVANCED PROPAGATION MODEL (APM) VER. 1.3.1 COMPUTER SOFTWARE CONFIGURATION ITEM (CSCI) DOCUMENTS**

**Authors:**
A. E. Barrios  
W. L. Patterson

**Performing Organization:**
SSC San Diego  
San Diego, CA 92152-5001

**Sponsoring/Monitoring Agency:**
Space and Naval Warfare Systems Command  
PMW–155  
4301 Pacific Highway  
San Diego, CA 92110-3127

**Distribution/Availabilty Statement:**
Approved for public release; distribution is unlimited.

**Abstract:**
This document describes the Advanced Propagation Model (APM) Version 1.3.1 computer software configuration item (CSCI) design and provides an input software requirement overview, a CSCI design architecture overview, and a detailed design description of each CSCI component.

**Subject Terms:**
Mission Area: Command, Control, and Communications  
electromagnetic propagation  
software requirements  
tactical fleet applications
