**ABSTRACT (Maximum 200 Words)**

Electron beam computed tomography (EBCT) is a noninvasive x-ray test like a CAT scan that detects calcium in the arteries of the heart. When calcium deposits are present, they indicate that some build-up of arterial blockages has begun in the arteries. The available evidence on EBCT shows that patients with calcium deposits are more likely to develop heart problems, such as heart attacks. There is controversy, however, because it is not clear whether EBCT is more accurate than traditional risk factor measurements for predicting who is most likely to develop heart disease. Some of the controversy has arisen because EBCT is expensive (about $500 per test). The test is also very sensitive, possibly too sensitive, meaning that many patients will have arterial abnormalities, but only some will ultimately experience problems with heart disease.

Because of its promise and uncertainties, the Army needs to understand whether EBCT is a better way to screen our personnel than our current methods. This study, which will enroll 2000 active duty Army personnel (men and women) between the ages of 40 and 45, will answer 3 important questions about the utility of EBCT as a screening test in our active-duty troops:

1. How common is coronary calcium in aged 40 to 45 year old active duty Army personnel? How does the expense and accuracy of an EBCT screening program compare to our current program of risk factor measurements?
2. Does finding coronary calcium on an EBCT provide patients with better information to help guide them to healthier and happier lifestyles compared to our current measurements, like cholesterol? Are patients more motivated to eat right and exercise, for example, when they know they have early arterial blockages?
3. Can we predict who will develop heart disease in the future better using an EBCT scan or a cholesterol measurement? Better predictions about heart disease risk will allow us to more accurately prescribe risk-reducing treatments like cholesterol medicines and aspirin.

This study will help the Army understand the full implications of this new test, EBCT, on the cardiovascular health of our active-duty force. This knowledge will help guide the Army's application of this technology within the cardiovascular screening program.

Introduction
The purpose of the Army’s cardiovascular screening program, initiated in 1981 and revised in 1989, was to reduce the incidence of sudden cardiac death associated with the mandatory semi-annual Army Physical Fitness Test. Despite mandatory screening for high risk individuals aged 40 years and older over the last decade, it does not appear that cardiovascular screening has had a major impact on sudden cardiac death of the middle aged U.S. Army soldier. This has prompted the Office of the Surgeon General, Department of the Army, to search for other screening tests for asymptomatic individuals. One such possibility is electron beam computed tomography (EBCT), which detects and quantifies coronary atherosclerotic burden in older populations through detection of coronary calcification. Civilian data, derived largely from selected, higher risk, and self-referred populations, are inadequate to assess the wide-scale application of this technology to lower risk individuals. To understand how EBCT might improve cardiovascular screening in the Army, the Prospective Army Coronary Calcium (PACC) study (a large, prospective, single center study) is investigating the relationship between EBCT findings, coronary risk behavior, and cardiovascular events, in young, asymptomatic U.S. Army personnel. This proposal focuses on evidence-based technology integration and preventive medicine. These aims have been endorsed by both the “Military Health Services System 2020 Report” and the Medical Research and Materiel Command “The Role of Technology in Reducing Health Care Costs” (MRMC white paper, October 1996) as major research initiatives for the future of military medicine.
The PACC study is addressing the following objectives:
1) To determine the prevalence, extent, and cost implications of the diagnosis of coronary calcification in asymptomatic active-duty military 40- to 45- year-old men and women undergoing routine cardiovascular screening.
2) To assess the impact of EBCT results on several dimensions of patient behavior for coronary risk factor modification, and its interaction with the CVSP.
3) To establish the relationship between EBCT coronary calcification and cardiovascular events in an unselected, low-risk military population.

Recent literature continues to support the continuation of the current study protocol. The primary aim of this study, to compare EBCT and the Framingham index for their prognostic utility in coronary heart disease, remains unanswered within the current literature.

As of September 5, 2002, 1840 participants have been enrolled in the cohort study (277 since last APR). This is substantial progress towards the goal of 2000 enrollees per the statement of work. The randomized trial cohort follow up was completed in March 2002. A total of 10 adverse events have been reported, none that were directly related to participation in the study. Each of these events represent natural history of coronary disease events, or evaluations for possible cardiac symptoms during the telephonic monitoring phase of the study.

The contract to SAR Inc. (employees handle data collection and management for the study) was renewed through MRMC as of August 2001 and is continuing.

The following amendments to the protocol have been completed in the past year:
   A. A serologic study of banked specimens to evaluate HDL kinetics.
   B. A request to use the ICDB to find eligible participants for direct mail advertisement.

Publications during 2001-2002:

Lee TC, O'Malley PG, Feuerstein IM, Taylor AJ. The prevalence and severity of coronary artery calcification on electron beam computed tomography in black and white subjects. J Am Coll Cardiol, In press.

Abstracts

Lee TC, O’Malley PG, Feuerstein I, Taylor AJ. Ethnicity and calcified atherosclerosis: Can data on coronary calcium be applied evenly across ethnic groups? Results from the Prospective Army Coronary Calcium Project. J Am Coll Cardiol 2002; 39:359A.
Key Research Accomplishments:

- Continued progress towards SOW goal of enrolling 2000 patients
- Completed follow-up of randomized trial (specific aim 2)
- Continued telephonic follow up of the existing cohort (enrolled to date)
Reportable Outcomes
Presentations and Publications: see above
Conclusions
Enrollment in the cohort study is nearing completion. Analysis of the randomized trial is actively underway. Continued subgroup analyses on questions of interest within the approved dataset are continuing.
