Death from cancer is most frequently caused by metastases. While research of the past 20 years has identified genes whose malfunction causes cancer to grow. It has not been clear why these defects also induce the ability to metastasize. We have defined molecules that form a connection between signals that make cancer cells grow and signals that cause them to metastasize. In breast cancer cells, a molecule called Akt kinase bridges these two functions. Here we study the exact mechanism by which Akt kinase connects mechanisms of growth with mechanisms of cancer spread. The identification of a single defined defect as responsible for growth and metastasis enhances our molecular insights into cancer and it defines candidate targets for therapeutic intervention.
Introduction

The defining characteristics of benign and malignant tumors are excessive growth and immortalization. In contrast, only malignant tumors express gene products that mediate invasiveness. Uncontrolled proliferation is a consequence of gain-of-function mutations of proto-oncogenes or loss-of-function mutations of tumor suppressor genes. Metastatic dissemination is a consequence of aberrant expression or splicing of stress response genes (Weber/Ashkar 2000). The consistent topology of metastasis formation by specific cancers, such as the high frequency of colony formation in bone and brain by malignant breast tumors, implies that metastasis gene expression is an inevitable consequence of gain of function by specific oncogenes. This raises the question: What molecular mechanisms connect the signal transduction pathways associated with dysregulated growth to the expression of metastasis genes in malignant, but not in benign tumors?

Receptor ligation by the epidermal growth factor can induce osteopontin gene expression (Malyankar et al. 1997; Atkins et al. 1997) through signal transduction that proceeds via protein kinase C and tyrosine kinases (Chackalaparampil et al. 1996). This implies that gain-of-function mutations in the EGF receptor pathway in breast cancer, causing dysregulated growth, may also mediate the over-expression of osteopontin, leading to dissemination. We find osteopontin to be constitutively expressed in malignant, but not in benign transformed breast cells. Here, we map the cause for this to constitutive activation of Akt kinase, an enzyme that is part of the EGF signaling pathway.
Specific Aim 1: Molecular characterization of the role of AKT in proliferation and induction of metastasis genes

Task 1: Transfection of Akt, dnAkt, constitutively active Akt, or vector control into breast epithelial cells. Cloning and characterization of the transfectants. Deliverable: Stably transfected cell lines. 3 months.

We stably transduced murine breast epithelial cells with various Akt kinase constructs. Benign cells were transfected with vector, wild-type Akt, or constitutively active Akt, while malignant cells were transfected with vector, wild-type Akt, or a dominant negative Akt mutant. The expression levels of the transfected genes were measured on the RNA and protein levels. Expectedly, osteopontin was constitutively expressed in Akt kinase-transduced cells and the constitutive osteopontin gene expression in malignant cells was suppressed by the dominant negative Akt kinase mutant according to RNAse protection assay, Northern blotting, and Western blotting. The levels of osteopontin induced by wild-type Akt and constitutively active Akt are comparable, likely reflecting the substantial overexpression. At these amounts, the baseline activity of wild-type Akt kinase is sufficient to transduce a signal. It may be important to note that the reduction of osteopontin gene expression by dominant negative Akt kinase is partial. Only moderate levels of over-expression can be achieved for dominant negative Akt kinase because this mutant also slows down cell divisions, consistent with the hypothesis that the constitutive activation of Akt kinase in MT2994 cells is causative for the transformation of these cells (Zhang et al. 2003, see Appendix).

Task 2: Analysis of the changes in osteopontin expression, expression of cyclins, and changes in cell cycle profile after transfection of Akt kinase, constitutively active Akt kinase, or dominant negative Akt kinase. Deliverable: Definition of the role of Akt in proliferation and osteopontin expression on the genetic level. 6 month.

In order to differentiate between osteopontin-dependent and osteopontin-independent consequences of Akt kinase overexpression we generated doubly transduced lines. Benign cells that stably expressed constitutively active Akt kinase were infected with a retrovirus containing osteopontin antisense. Similarly, we generated malignant
dominant negative Akt/osteopontin cells. All relevant singly and doubly transfected controls were included. As before, the expression levels of the modulated genes were measured by Western blotting. The elevated osteopontin expression in transfectants of constitutively active Akt kinase could be reversed by co-transfection of antisense osteopontin, and the suppression of osteopontin by dominant negative Akt was reversed by co-transfection with the osteopontin gene. We tested the growth rates of doubly transduced cells by plating 5000 cells per well in 24-well plates followed by daily cell counts in quintuplicates. Remarkably, within only one day, transfection of constitutively active Akt kinase into benign cells significantly induced the growth rate, while transfection of dominant negative Akt kinase into malignant cells significantly reduced it. The differences remained significant throughout the four days of measurement. In contrast, the stable transfection of osteopontin into cells overexpressing dominant negative Akt kinase or of osteopontin antisense into cells overexpressing constitutively active Akt kinase had no effect on the growth rates. We also analyzed cell motility by in vitro wounding and transwell chemokinesis. Benign cells transfected with constitutively active Akt displayed enhanced migration. Co-transfected osteopontin antisense completely reversed this effect (Zhang et al. 2003, see Appendix). These results are consistent with osteopontin-independent roles of Akt as a growth promoting gene product and osteopontin-dependent roles of Akt as a migration promoting gene product.

Specific Aim 2: Identification of downstream targets of Akt in osteopontin induction and cell cycle progression.

Task 4: Cloning of the osteopontin promoter into a reporter construct and investigation into reporter activity in various transfectants of Akt, constitutively active Akt, or dominant negative Akt. Electrophoretic mobility shift assays of nuclear extracts from the transfectants with oligonucleotides derived from the osteopontin promoter. Deliverable: Identification of Akt-induced transcription factors that mediate osteopontin gene expression. 8 months.

Previous studies have shown that the induction of osteopontin in renal epithelial cells by TGF-β or EGF is caused by increased transcription (Malyankar et al. 1997). Akt kinase activity has previously been associated with activation of the AP-1 transcription
factor and Ets-family transcription factors, both of which are known to bind to the osteopontin promoter. We set out to further map the molecular connections between Akt kinase activity and osteopontin transcription in breast epithelial cells. For this purpose, we took advantage of the breast epithelial cell lines constitutively expressing various Akt constructs that we had generated. We used benign cells stably expressing wild-type Akt kinase, constitutively active Akt kinase, or vector in luciferase reporter assays under the control of full length or truncated osteopontin promoter sequences. Expectedly, Akt kinase activity can induce the transactivation of the osteopontin promoter (Zhang et al. 2003, see Appendix). The Akt responsive promoter domain was mapped to a region between base −600 and base −777. Consistent with a previous report (Guo et al. 1995), a far distal promoter element (between bases −777 and -882) appeared to contain a repressor.

Specific Aim 3: Analysis of metastatic potential dependent on Akt and osteopontin

Task 5: Study of colony formation of transfected cells (vector, Akt, constitutively active Akt, dominant negative Akt) in soft agar in the presence or absence of anti-OPN antibody or after co-transfection with osteopontin antisense. Deliverable: Data on dependence of growth in soft agar on Akt and osteopontin. 3 months.

Because osteopontin is necessary for soft agar colony formation and Akt kinase induces osteopontin expression we asked whether the constitutive over-expression of Akt kinase in benign cells was sufficient to convey the ability of anchorage independent growth. Expectedly, Akt transfected breast epithelial cells displayed clone formation in soft agar, whereas vector transfected cells did not. The repeated addition of an anti-osteopontin antibody to the cell culture reduced the numbers and sizes of clones formed. In contrast, a control immunoglobulin had no effect (Zhang et al. 2003, see Appendix). We also analyzed the doubly transduced cells for colony formation in soft agar. Co-expression of osteopontin antisense in constitutively active Akt expressing cells lead to a partial reduction of colony formation, while cells transduced with vector constructs did not form clones in soft agar. In a complementary approach, the expression of dominant negative Akt in malignant cells caused a partial reduction in the numbers and sizes of
clones formed. Co-expression of osteopontin virtually completely reversed this inhibition (Zhang et al. 2003, see Appendix).

**Task 6:** In vivo analysis of dissemination of cells transfected with Akt, constitutively active Akt, dominant negative Akt, vector control after orthotopic injection. Deliverable: Data on dependence of metastasis formation on Akt and osteopontin. 9 months. This task will use a maximum of 100 mice.

We tested in vivo tumorigenesis and dissemination by the doubly transduced benign cells. Expectedly, the vector/vector and vector/antisense osteopontin transduced cells generated small hyperplastic lesions. In contrast, caAkt expressing cells generated larger tumors. Only the cells containing Akt plus vector, but not the cells expressing Akt plus antisense osteopontin, formed distal lesions (Zhang et al. 2003, see Appendix).
Key Research Accomplishments

* We have identified the constitutive activation of Akt kinase as a molecular defect in malignant breast cancer.

* Our laboratory and others have shown that osteopontin gene expression is essential for generating a malignant phenotype in breast tumors.

* We have found osteopontin gene expression to be a downstream target of Akt activity.

* We can differentiate two signal transduction cascades downstream of Akt that lead to either growth dysregulation or invasiveness.
Reportable Outcomes

Conclusions

Like other aspects of cancer, metastasis is caused by the dysregulation of specific genes.

Metastasis genes are stress response genes, which suggests that malignancy constitutes mimicry of leukocyte homing.

In cancer, metastasis genes are aberrantly expressed or spliced.

The dysregulation of metastasis genes in cancer occurs secondary to oncogene activation.

Received 10 December 2002/Returned for modification 20 February 2003/Accepted 19 June 2003

Malignant tumors are characterized by excessive growth, immortalization, and metastatic spread, whereas benign tumors do not express gene products that mediate invasion. The molecular basis for this difference is incompletely understood. We have screened signal transduction molecules associated with the epidermal growth factor (EGF) receptor and have identified constitutive phosphorylation, indicative of activation, of Akt kinase in MT2994 breast cancer cells. In contrast, cells of the benign breast epithelial cell lines Comma-D and FSK-7 are immortalized through pathways that are independent of the EGF–phosphatidylinositol 3-kinase–Akt kinase cascade, but this is not associated with invasiveness. Transfection of constitutively active Akt kinase causes accelerated cell division and osteopontin expression. Conversely, dominant-negative Akt kinase slows cell cycle progression and suppresses osteopontin expression. The manipulation of osteopontin expression in this setting by transfection of the gene or its antisense does not affect the growth rate of the cells but alters cell motility and anchorage independence. Therefore, Akt kinase activates two distinct genetic programs: the program of growth and survival, which is independent of osteopontin expression, and the program of invasiveness and anchorage independence, which is mediated by osteopontin. These studies define Akt kinase as a molecular bridge between cell cycle progression and dissemination.

Fn1 The defining characteristics of benign and malignant tumors are excessive growth and immortalization. In contrast, only malignant tumors express gene products that mediate invasiveness. Uncontrolled proliferation is a consequence of gain-of-function mutations of proto-oncogenes or loss-of-function mutations of tumor suppressor genes. Metastatic dissemination is a consequence of aberrant expression or splicing of stress response genes (53). The consistent topologi of metastasis formation by specific cancers, such as the high frequency of colony formation in bone and brain by malignant breast tumors, implies that metastasis gene expression is an inevitable consequence of gain of function by specific oncogenes. This raises the following question: what molecular mechanisms connect the signal transduction pathways associated with dysregulated growth to the expression of metastasis genes in malignant but not in benign tumors?

Gain-of-function mutations in the epidermal growth factor (EGF) family of receptors and their associated pathways of signal transduction often underlie the transformation of breast tissue, as is evidenced by the cases of breast cancers that overexpress the EGF family receptor Her-2/neu. This dysregulation is also prominent in steroid hormone-independent breast cancer, where excessive activation of EGF receptor pathways may be the only driving force for cell cycle progression (5). The intracellular signal transduction associated with members of the EGF receptor family is mediated by multiple proto-oncogenes, including protein kinase C, phosphatidylinositol 3-kinase (PI 3-kinase), and Akt kinase (31, 35). Their constitutive activation occurs as a consequence of over-expression of Her-2/neu (6, 24, 33, 41, 56) and may be sufficient to cause transformation.

Expression of the cytokine osteopontin is necessary and may be sufficient for the formation of metastases by breast cancer. High levels of osteopontin in the disease are an adverse prognostic factor (42, 45). Multiple metastatic breast cancer cell lines express osteopontin, and transfection of the osteopontin gene into weakly tumorigenic human breast tumor cell lines confers invasive behavior (47, 50, 51). Increasing the expression of osteopontin or transfection of osteopontin-encoding cDNA into a previously benign cell line is sufficient to produce a metastatic phenotype in a rat mammary model (38). Short regulatory DNAs exist in human cancer cells that can be transferred into model rat mammary cell lines and can induce metastatic spread. These noncoding fragments of DNA act via the common effector gene osteopontin (4, 11, 19, 20).

Receptor ligation by EGF can induce osteopontin gene expression (2, 34) through signal transduction that proceeds via protein kinase C and tyrosine kinases (8). This implies that gain-of-function mutations in the EGF receptor pathway in breast cancer, causing dysregulated growth, may also mediate the overexpression of osteopontin, leading to dissemination. We find osteopontin to be constitutively expressed in malignant but not in benign transformed breast cells. Here, we trace the cause for this to constitutive activation of Akt kinase, an enzyme that is part of the EGF signaling pathway.
2 ZHANG ET AL.

MATERIALS AND METHODS

Cells. We used three murine BALB/c breast tumor cell lines with various levels of malignancy (3, 26, 29, 39). Comma-D cells are derived from culture of mid-pregnancy mammary glands and develop hyperplasia when injected into mice. FSK-7 cells were obtained from primary breast cancer cell culture. MT2994 cells were selected from mammary tumors that had been induced by DMBA. Among these cells, only MT2994 is malignant in vivo. Even though these cell lines were derived from various mice at various time points, their shared inbred genomic background (the BALB/c strain) allows them to be viewed as a progression series of breast tumor cell lines. The cells were grown in MDCL medium (Dulbecco's modified Eagle's medium Hams F12 balance [1:1] with 2% adult bovine serum, 5 μg of EGF/ml, and 10 μg of insulin/ml). For growth factor deprivation, the medium was made without serum, EGF, and insulin.

Induction of growth factor signaling. Cells were plated at 5 × 10^4 per well in 6-well plates. After 7 h, cultures were washed twice with phosphate-buffered saline and maintained in growth factor-deprived medium (containing 0.05% bovine serum albumin) for 14 h. The cells were then stimulated with the indicated amounts of EGF (obtained from Sigma, St. Louis, Mo.) for the indicated time frames before harvesting and analysis.

To assess candidate signal transduction molecules involved in the induction of osteopontin gene expression, specific inhibitors were added to the cells. The PI 3-kinase inhibitor wortmannin and the phosphoinositol C (PLC) inhibitor U73122 were purchased from CalBiochem (San Diego, Calif.). The cells were pretreated with the respective inhibitors or vehicle (dimethyl sulfoxide) alone for 30 min and then cocreated with EGF for an additional 8 h. Preliminary dose-response experiments had established that the concentrations of 100 nM wortmannin and 500 nM U73122 were effective and nontoxic.

For the investigation of cell growth rates, each cell line was plated at 5,000 cells in 24-well plates. Daily, five wells per group were harvested by trypsinization, and the cell numbers were determined in a Coulter Z-Series Counter. At each time point, the cell numbers from the five wells of the various groups of transfectants were analyzed for statistically significant differences by the Wilcoxon-Mann-Whitney test, by accepting a probability of error of <0.05.

RNA protection assay. Osteopontin expression was analyzed by an RNAse protection assay on total RNA by using a 400-bp probe from the 5′ region of the transcript and controlling for loading with a probe for β-actin. Total RNA was isolated using the RNeasy Mini Kit (Qiagen GmbH, Hilden, Germany), and its amount and purity were confirmed by spectrophotometry. The RNA protection assay was performed with a commercial kit (Ambion). Briefly, [α-32P]UTP-labeled probes were mixed with sample RNA and coprecipitated. Hybridization proceeded for 10 min at 68°C, followed by digestion of the unproctected RNA with RNase A-T1 for 30 min at 37°C and separation of the hybridized RNA on 5% acrylamide-8 M urea gels. The gels were dried on filter paper in a gel dryer (Bio-Rad) and exposed to X-ray film. Autoradiograms were scanned using an Alpha-Imag 2200 spot density analyzer (Bio-Image Ltd, Cambridge, Mass.), and the integrated densities of areas were recorded.

Northern blotting. Total RNA was isolated using the RNeasy Mini Kit (Qiagen GmbH) according to the manufacturer’s instructions. Purify and yield were confirmed by spectrophotometry at 260 and 280 nm. Ten micrograms of RNA was denatured and separated on formaldehyde-containing 1.2% agarose gels by electrophoresis, blotted onto nylon membranes (Amersham), and probed with a 32P-labeled osteopontin cDNA probe (generated by PCR using forward primer 5′-GGCAATCTGCTTATGAGCTGGTTC-3′ and reverse primer 5′-ATGAGTCCGGAACTGTCCTGTCCT-3′) or a 3684 cDNA probe (generously provided by Goebberd Dittm). Hybridization of the probe to the RNA was allowed to proceed overnight, and the membranes were washed and exposed to X-ray film at −80°C before development.

Immunoblot assay. For analysis of secreted osteopontin, the growth factor-deprived cell culture supernatant was collected from each treatment group. Forty microliters of supernatant per sample was electrophoresed on sodium dodecyl sulfate (SDS)-10% polyacrylamide minigels with nonreducing sample buffer. For analysis of intracellular proteins, cells were lysed in radioimmunoprecipitation assay buffer (50 mM Tris-HCl [pH 7.5], 150 mM NaCl, 1% NP-40, 0.5% sodium deoxycholate, 0.1% SDS) for the osteopontin blot or Akt kinase blot or in NP-40 buffer (150 mM NaCl, 1 mM EDTA, 20 mM Tris-HCl [pH 8.0], 0.5% NP-40) for the phospho-Akt blot. Cell lysates at equal amounts of protein (10 to 20 μg/lane) were electrophoresed on reducing SDS–10% polyacrylamide gels. The separated proteins were transferred to Pure Nitrocellulose membranes (Schleicher & Schuell) and blocked with antibodies to osteopontin (R&D Systems), Akt, and Akt phosphorylated at Ser473 (New England Biolabs, Beverly, Mass.). Detection was accomplished with the ECL chemiluminescence reagent.

REPORTER ASSAYS. Comma-D cells stably transfected with vector, wild-type Akt, or constitutively active Akt were plated at 5 × 10^5 cells per 60-mm-diameter petri dish and grown for 24 h before transfection with Fugene. Various reporter constructs containing the luciferase gene reporter under the control of truncation mutants of the osteopontin promoter were used at 2 μg per transfection. The common internal transfection standard pRL-SV40 (10 ng per transfection) served as a control for transfection efficiency. Twenty-four hours after transfection, the cells were harvested in 0.4 ml of reporter lysis buffer (Promega), and dual luciferase reporter assays were performed by following the protocol provided by the manufacturer. Forty microliters of lysate was used for measurement in a luminometer (Turner Designs TD-20/20). Three separate experiments were performed, and results were calculated as means ± standard deviations. The length of the osteopontin promoter fragments tested was −88 to +79, −258 to +79, −472 to +79, −600 to +79, −777 to −79, and −882 to +79 (23). DNA constructs and infection. The constructs of Akt kinase, constitutively active Akt kinase, and dominant-negative Akt kinase (K179M) in the pCMV-6 vector or in the retrovirus vector pLNCX were generously provided by Thomas Franke (12, 33) (the constitutively active Akt kinase was cloned into pLNCX in our laboratory). The construct for expression of the mouse osteopontin coding sequence was obtained by reverse transcription-PCR from osteosarcoma cells by using the sense primer 5′-ATGGATCCCGCAGATGTTGGGAC-3′ and the antisense primer 5′-GCAATTTGGACCTTTTGCTCT-3′. The resultant BamHI-EcoRI cDNA fragment was ligated into the retrovirus vector pLNCX. The construct for expression of osteopontin antisense cDNA generated by PCR, was ligated in the antisense orientation into the EcoRI and BamHI sites of pLNCX. The integrity of all constructs was confirmed by DNA sequencing. The packaging cell line tas54 was used to generate high-titer retrovirus (16) for infection of all breast epithelial cell lines. Ten micrograms of each retrovirus construct was coinjected with 10 μg of the pLNCX packaging vector was transduced into tas54 cells by the calcium phosphate coprecipitation method, and the culture supernatant was collected on the day following transfection. In order to generate stable Akt transfectants, the murine breast tumor cell lines were infected with virus-containing supernatants in the presence of 8 μg of Polybrene (Sigma) per ml. Infected cells were selected in MDCL medium with 5 μg/ml geneticin (G418) for 4 to 5 days, followed by analysis of RNA and protein expression. Several clones were selected and characterized for all single infectants, while the doubly transduced cells were selected and analyzed in bulk.

The cell motility experiment is often referred to as an “in vitro wounding assay” (21, 27) because a cell monolayer is disrupted and the rate of repopulation is assessed. Breast epithelial cells were plated at 2.5 × 10^5 per 100-mm-diameter petri dish. After 2 days, they were grown in growth-factor-deprived medium for 24 h. The cultured cells were disrupted by scratching with a 220-μm pipet tip. Repopulation of the cell-free area was analyzed under an inverted microscope after 22 h. In this time frame, cell division is negligible in growth factor-deprived medium.

Soft-agar growth. Cells (3 × 10^5 per 60-mm-diameter dish) were plated in triplicate with a top layer of 0.3% agar (Bacto Agar; Difco, Detroit, Mich.) and a bottom layer of 0.5% agar (both in MEM medium). Every other day, 0.3 ml of MEM medium was supplemented and the plates were examined microscopically for growth. After 3 weeks, the number of cell clusters per microscopic field and the number of cells per cluster were counted in five views per plate (one central, four peripheral), and cell clusters were photographed. Soft-agar assay conditions have not been standardized because they depend on the specific cell lines under study. The size of the cell clusters obtained differs widely with the cell lines used; cell clusters may comprise fewer than 10 cells (7, 25) or reach microscopically (36) or microscopically (43) viable diameters. For Comma-D cells transfected with Akt, an incubation time of 3 weeks before enumeration has been found suitable (40). We chose to determine the frequency of clones formed and the clone size (numbers of cells per cluster). At the plating density used in the time frame outlined here, the detection of a clone in radioimmunoprecipitation quantitation was conducted separately, and the resulting histograms of cluster size and frequency were considered to be more informative than the simple determination of cluster sizes at a randomly chosen size. The resulting histograms are characteristic of the individual cell lines and were analyzed for statistical differences in variance by the F-test, by accepting a probability of error of 1, 5, or 10% with a one-tailed test. The results were confirmed with an automated image analysis system (Optronics). The resulting histograms of cluster size and frequency were considered to be more informative than the simple determination of cluster sizes at a randomly chosen size. The resulting histograms are characteristic of the individual cell lines and were analyzed for statistical differences in variance by the F-test, by accepting a probability of error of 1, 5, or 10% with a one-tailed test. The results were confirmed with an automated image analysis system (Optronics).
FIG. 1. Constitutive osteopontin expression contributes to a malignant phenotype in breast tumors. (A) MT2994 cells or FSK-7 cells (0.5 × 10^6) were injected orthotopically into the left inguinal mammary fat pads of BALB/c mice. After 21 days, the mice were analyzed for tumor formation and metastasis. The upper panel shows the livers and gastrointestinal tracts; the lower panel depicts the opened abdomens. Arrows point to metastases. Thick arrows indicate the primary tumors (in MT2994 cells) or hyperplasias (in FSK-7 cells). These results are representative for 10 mice in each group. (B) Cells were maintained under growth factor-deprived conditions in the presence or absence of EGF for 14 h. Supernatants were collected, and cells were lysed. Osteopontin (OPN) expression was assessed on the RNA level by an RNase protection assay (using β-actin as a loading control) and on the protein level by Western blotting (using tubulin as a loading control for the cell lysates). (C) MT2994 cells (5 × 10^6 cells/60-mm-diameter petri dish) were grown in soft agar in the absence of antibodies (back row, MT2994) or in the presence of an anti-osteopontin antibody (third row from front, MT + anti-OPN) for 21 days. The frequency of clone formation and clone size (number of cells per cluster) were enumerated in five random microscopic fields. While control immunoglobulin had no effect (data not shown), the anti-osteopontin antibody suppressed clone formation. Comma-D cells and FSK-7 cells do not constitutively secrete osteopontin and do not form clones in soft agar when grown under identical conditions (front rows, FSK-7 and Comma-D).
acncopy was performed for the detection of primary tumors or hyperplasia and metastases. To ascertain that the FSK-7 cells were free of murine pathogens, serum samples from injected animals were tested for Sendai virus, pneumonia virus of mice, mouse hepatitis virus, minute virus of mice, Thelers’s murine encephalomyelitis virus, reovirus, Mycoplasma pulmonis, mouse parvovirus, epizootic diarrhea of infant mice virus, lymphocytic choriomeningitis virus, mouse adenovirus, encephalomyelitis (mousepox virus), K virus, polyomavirus, mouse thymic virus, mouse cytomegalovirus, hantavirus, Encephalitis zoon cuniculi, and CAR bacillus. Results of serological testing were negative in all instances. The in vivo experiments were performed under a protocol approved by the institutional animal care and use committee at Tufts-New England Medical Center.

RESULTS

The malignant phenotype is associated with constitutive osteopontin expression in breast tumor cells. MT2994 cells formed disseminating tumors after orthotopic injection, whereas FSK-7 cells showed modest local growth, diagnosed as hyperplasia, that did not develop into tumors and did not spread beyond the site of injection (Fig. 1A). Comma-D cells and FSK-7 cells secreted osteopontin in EGF-containing medium. Under growth factor-deprived conditions, no osteopontin RNA or protein expression was detectable. In contrast, MT2994 cells had high constitutive levels of osteopontin, regardless of the presence or absence of growth factors (Fig. 1B). Soft-agar colony formation measures the ability of cells to grow independently of anchorage and correlates well with the capacity of tumor cells for invasiveness in vivo (55). We hypothesized that the importance of osteopontin for the dissemination of breast cancer cells would also be reflected in an essential contribution by this molecule to soft-agar colony formation. In initial experiments, we asked whether malignant cells form clones in soft agar in an osteopontin-dependent fashion. As expected, the benign Comma-D and FSK-7 cells did not form clones under these conditions. MT2994 cells formed clones in soft agar in a manner that was specifically inhibitable by addition of an anti-osteopontin antibody (Fig. 1C). Hence, we set out to analyze the molecular mechanisms of osteopontin induction in breast cancer cells.

Osteopontin gene expression is linked to the activation of growth factor signaling. We asked whether osteopontin gene expression by breast tumor cells is secondary to activation of
growth factor signaling pathways. The elimination of growth factors from the medium reduced the expression of osteopontin in the benign breast epithelial cell lines Comma-D and FSK-7 but not in the malignant breast tumor line MT2994. Conversely, stimulation of the cells with EGF induced osteopontin expression in Comma-D cells and FSK-7 cells in a time- and dose-dependent manner but did not affect osteopontin expression in MT2994 cells (Fig. 2A and B). To quantitate this observation, we performed densitometry of osteopontin on the Western blots of cell lysates and supernatants and calculated the total amounts of osteopontin protein per cell culture dish (5 x 10^5 cells) consequent to the titration of EGF. At 200 ng of EGF/ml over 8 h, the levels of osteopontin expression in Comma-D cells and FSK-7 cells are about one-half of those in MT2994 cells. In the latter cell line, the osteopontin expression levels are not further induced by EGF (Fig. 2C).

Differences in osteopontin expression between the benign and malignant cell lines were also confirmed by fluorescent microscopy with a biotinylated anti-osteopontin antibody (R&D Systems) and streptavidin-phycocyanin. The nuclei were stained with 4',6'-diamidino-2-phenylindole (DAPI), and the cytoplasm was stained with fluorescein isothiocyanate (FITC)-conjugated anti-β-actin. The signal for osteopontin was constitutive in MT2994 cells in growth factor-deprived medium and was not further enhanced by the addition of exogenous EGF. In contrast, Comma-D cells and FSK-7 cells (data not shown) depended on the addition of growth factors in the medium for significant osteopontin staining (Fig. 2D). The location of the osteopontin signal was predominantly perinuclear, which is characteristic of secreted proteins (15).

The constitutive osteopontin expression in malignant breast epithelial cells correlates with a gain of function in the PI 3-kinase pathway. We analyzed the involvement of signal transduction molecules associated with the EGF receptor in the induction of osteopontin gene expression. Addition of the PLC inhibitor U73122 or the PI 3-kinase inhibitor wortmannin reversed the EGF-mediated increase in osteopontin mRNA levels in Comma-D and FSK-7 cells. In contrast, the high abundance of osteopontin mRNA in MT2994 cells remained unaffected by either inhibitor (Fig. 3A).

Because wortmannin could not reverse the constitutive osteopontin gene expression in MT2994 cells, the defect leading to its up-regulation was likely to be downstream of PI 3-kinase. PI 3-kinase can phosphorylate and activate Akt kinase. In malignant cells, Akt kinase activity may be elevated due to phosphorylation on serine 473 and threonine 308. We therefore tested Akt phosphorylation in the breast tumor cells on Western blots with a phospho-Akt-specific antibody. Stripping and reprobing for total Akt kinase and for tubulin served as controls for Akt expression levels and for equal loading of the gels, respectively. Akt was constitutively phosphorylated in the malignant cell line MT2994 but not in Comma-D or FSK-7 cells, where Akt kinase phosphorylation was EGF induced and transient. This is not accounted for by overexpression of the kinase, because levels of total Akt were not higher in MT2994 cells than in Comma-D or FSK-7 cells (Fig. 3B).

Overexpression of Akt kinase induces osteopontin gene expression. To gain further mechanistic insight into the contributions by Akt kinase to osteopontin gene expression, we stably transduced the breast epithelial cells with various Akt kinase constructs. Comma-D cells were transfected with vector, wild-type Akt, or constitutively active Akt. FSK-7 cells were transfected with vector or constitutively active Akt. MT2994 cells were transfected with vector, wild-type Akt, or a
dominant-negative Akt mutant. The expression levels of the transfected genes were measured on the RNA and protein levels. As expected, osteopontin was constitutively expressed in Akt kinase-transduced Comma-D cells and FSK-7 cells, while the constitutive osteopontin gene expression in MT2994 cells was suppressed by the dominant-negative Akt kinase mutant, as shown by an RNase protection assay and Western blotting (Fig. 4A). We confirmed the osteopontin message levels by Northern blotting (with 36B4 as a loading control) and found this measurement to be in good correlation with the RNase protection assay results (Fig. 4B). The levels of osteopontin induced by wild-type Akt and constitutively active Akt are comparable, likely reflecting the substantial overexpression of Akt kinase. At these amounts, the baseline activity of wild-type Akt kinase is sufficient to transduce a signal. It should be noted that the reduction of osteopontin gene expression by dominant-negative Akt kinase is partial. Only moderate levels of overexpression can be achieved for dominant-negative Akt kinase, because this mutant also slows down cell division (compare Fig. 5B below), consistent with the hypothesis that the
GROWTH FACTOR SIGNALING INDUCES METASTASIS GENES

constitutive activation of Akt kinase in MT2994 cells is causative for the transformation of these cells.

Previous studies have shown that the induction of osteopontin in renal epithelial cells by transforming growth factor β or EGF is caused by increased transcription (34). Akt kinase activity has previously been associated with activation of the AP-1 transcription factor and Ets family transcription factors (17, 18, 28), both of which are known to bind to the osteopontin promoter (reviewed in reference 52). We set out to further map the molecular connections between Akt kinase activity and osteopontin transcription in breast epithelial cells. For this purpose, we took advantage of the breast epithelial cell lines constitutively expressing various Akt constructs that we had generated. We used Comma-D cells stably expressing wild-type Akt kinase, constitutively active Akt kinase, or vector in luciferase reporter assays under the control of full-length or truncated osteopontin promoter sequences. As expected, Akt kinase activity can induce the transactivation of the osteopontin promoter (Fig. 4C). The Akt-responsive promoter domain was mapped to a region between base −600 and base −777. Consistent with a previous report (23), a far-distal promoter element (between bases −777 and −882) appeared to contain a repressor.

Akt kinase enhances the growth rate through osteopontin-independent pathways and mediates migration through osteopontin. In order to differentiate between osteopontin-de-

Fig. 4. Akt kinase activity induces osteopontin gene expression. (A) Following serum starvation for 14 h, the transfected breast epithelial cells were grown under growth factor-deprived conditions, stimulated by EGF, or kept in normal growth medium containing 2% adult bovine serum, EGF, and insulin (MECL). Osteopontin (OPN) expression was analyzed by an RNase protection assay, and a probe for β-actin was used to control for loading. RDU ratio, relative density units of osteopontin RNA divided by those of actin RNA. The results were confirmed by analysis on the protein level by immunoblotting of cell culture supernatants. Overexpression of the transfected Akt constructs was confirmed by Western blotting using cell lysates. Lysates from transiently transfected 293T cells confirmed the integrity of the transfected DNA constructs (data not shown). The levels of resulting Akt phosphorylation were tested with a phospho-Akt (P-Akt)-specific antibody. Tubulin served as a loading control. wt-Akt, wild-type Akt; ca-Akt, constitutively active Akt; dn-Akt, dominant-negative Akt. (B) The results from the RNA protection assay were confirmed by Northern blotting on total RNA from cells transfected with various Akt constructs (ca-Akt, wt-Akt, and dn-Akt). The cells had been cultured in complete medium (MECL) or in serum-free medium with or without EGF. The blot was probed for osteopontin and for 36B4 (loading control). Similar results were obtained with additional clones of ca-Akt-transfected FSK-7 cells and dn-Akt-transfected MT2994 cells (data not shown). (C) Reporter assays with osteopontin promoter constructs. Comma-D cells stably expressing wild type Akt kinase (Wt-Akt), constitutively active Akt kinase (CA-Akt), or the vector control were transiently transfected with luciferase (luc) reporter constructs under the control of various fragments of the osteopontin promoter. The lengths of the osteopontin promoter truncation mutants tested were −85 to +79 (OPN-luc1), −258 to +79 (OPN-luc2), −472 to +79 (OPN-luc3), −600 to +79 (OPN-luc4), −777 to +79 (OPN-luc5), and −882 to +79 (OPN-luc6). With OPN-luc5, the data for Wt-Akt and for CA-Akt are significantly different from the data for the vector control (P < 0.05 [asterisked] according to the t test for paired samples, after testing for normal distribution and equal variance). Luciferase activity is expressed in relative units, with the activity of the vector-transfected Comma-D cells set at 1. Data reflect averages of three independent experiments. Error bars, standard deviations.
FIG. 5. Osteopontin is a downstream effector of Akt kinase for migration but not for growth. (A) After serum starvation for 14 h, transfected breast epithelial cells were grown under growth factor-deprived conditions or kept in normal growth medium (MECL). Overexpression of the transfected constructs was confirmed by Western blotting using cell lysates and cell culture supernatants from transduced FSK-7 or MT2994 cells. Expression of the transfected Akt constructs was analyzed by Western blotting with anti-hemyagglutinin or anti-Akt kinase. Tubulin served as a loading control. Osteopontin expression levels were measured by probing blots of cell lysates and supernatants with a specific anti-osteopontin antibody. ca-Akt, constitutively active Akt kinase; dn-Akt, dominant-negative Akt kinase; OPN, osteopontin; as-OPN, osteopontin antisense. (B) Akt kinase induces cell growth independently of osteopontin. Cells were plated at 5 × 10^5 per well in 24-well plates. Cell numbers per well were determined daily using a Coulter Z Series cell counter. Each data point represents the mean ± standard deviation of five measurements. Data points labeled with an asterisk are significantly different (P < 0.05) from the other data sets. V, vector transfectant; CA, transfectant of constitutively active Akt kinase; DN, transfectant of dominant-negative Akt kinase; OPN, transfectant of osteopontin; AS-OPN, transfectant of osteopontin antisense). (C) Constitutive osteopontin expression is necessary for cell motility. Transduced FSK-7 cells were plated at 2.5 × 10^4 per 100-mm-diameter dish. After 2 days, they were grown in growth factor-deprived medium for 24 h. The cultured cells were disrupted by scratching with a Pipetman equipped with a 1,000-μl tip. Repopulation of the cell-free area was examined under an inverted microscope after 22 h. Transfectants with constitutively active Akt (CA-AKT) sprout into the depleted area (arrows, top left). A higher magnification shows the reorientation of the cells (arrows, top right). No substantial changes are seen in cells transduced with constitutively active Akt plus antisense osteopontin (CA-AKT + AS-OPN) (bottom left) or vector controls (V + V) (bottom right). Similar results were obtained in three additional experiments.

dependent and osteopontin-independent consequences of Akt kinase overexpression, we generated doubly transduced lines. FSK-7 cells that stably expressed constitutively active Akt kinase were infected with a retrovirus containing osteopontin antisense, yielding FSK-7 vector plus vector, FSK-7 constitutively active Akt plus vector, and FSK-7 constitutively active Akt plus antisense osteopontin cells. Similarly, we generated MT2994 vector plus vector, MT2994 dominant-negative Akt
plus vector, and MT2994 dominant-negative Akt plus osteopontin cells. As before, the expression levels of the modulated osteopontin genes were measured by Western blotting. The elevated osteopontin expression in transfectants of constitutively active Akt kinase could be reversed by cotransfection of antisense osteopontin, and the suppression of osteopontin by dominant-negative Akt was reversed by cotransfection with the osteopontin gene (Fig. 5A).

We tested the growth rates of doubly transduced cells by plating 5,000 cells per well in 24-well plates, followed by daily cell counts in quintuplicate. Remarkably, within only 1 day, transfection of constitutively active Akt kinase into FSK-7 cells significantly induced the growth rate, while transfection of dominant-negative Akt kinase into MT2994 cells significantly reduced it. The differences remained significant throughout the 4 days of measurement. In contrast, the stable transfection of osteopontin into cells overexpressing dominant-negative Akt kinase or of osteopontin antisense into cells overexpressing constitutively active Akt kinase had no effect on the growth rates (Fig. 5B). Identical results were obtained with singly transduced FSK-7 cells expressing constitutively active Akt kinase and MT2994 cells expressing dominant-negative Akt kinase (data not shown).

We also analyzed cell motility in vitro. Doubly transduced FSK-7 cells were plated at 2.5 x 10^5 per 100-mm-diameter dish and grown for 2 days. They were starved for 24 h in growth factor-deprived medium. The geometry of the cell culture was disturbed by scratching across the diameter of the cell culture dish. After 22 h, FSK-7 cells transfected with constitutively active Akt displayed reorientation and migration into the space between the continuous layers. Cotransfected osteopontin antisense completely reversed this effect, and like cells transfected with the vector control, these cells did not move (Fig. 5C). For a more quantitative analysis of cell motility, we performed a transwell chamber chemokinesis assay with coating of both sides of the membrane with 10 μg of fibronectin/ml. A total of 2.5 x 10^6 cells were placed in the upper chamber, and serum- and growth factor-free medium was placed in both compartments. After 4 h, the numbers of cells per optical field on the lower side of the membrane were 9 ± 2 for FSK-7 vector plus vector, 19 ± 6 for FSK-7 vector plus antisense osteopontin, 51 ± 2 for FSK-7 constitutively active Akt plus vector, and 32 ± 4 for FSK-7 constitutively active Akt plus antisense osteopontin. These results are consistent with osteopontin-independent roles of Akt as a growth-promoting gene product and osteopontin-dependent roles of Akt as a migration-promoting gene product.

**Osteopontin-dependent and -independent pathways contribute to generating a malignant phenotype.** Because osteopontin is necessary for soft-agar colony formation (see Fig. 1C) and Akt kinase induces osteopontin expression, we asked whether the constitutive overexpression of Akt kinase in FSK-7 cells was sufficient to confer anchorage-independent growth. As expected, Akt-transfected FSK-7 cells displayed clone formation in soft agar, whereas vector-transfected FSK-7 cells did not. The repeated addition of an anti-osteopontin antibody to the cell culture reduced the numbers and sizes of clones formed. In contrast, a control immunoglobulin had no effect (Fig. 6A). As in the preceding experiment (compare Fig. 1C), the inhibition of clone formation by an anti-osteopontin antibody was partial, a finding which may reflect limitations in the neutralization by the antibody. We therefore analyzed the doubly transduced cells for colony formation in soft agar. Coexpression of osteopontin antisense in FSK-7 cells expressing constitutively active Akt led to a partial reduction in colony formation. Consistent with the earlier results, FSK-7 cells
FIG. 6
FIG. 6. Invasive growth depends on Akt kinase and osteopontin. (A) FSK-7 cells stably transfected with vector or with myr-Akt were plated in soft agar with repeated additions of either an anti-osteopontin antibody or a control immunoglobulin. After 21 days, the frequency of clone formation and the clone size (numbers of cells per cluster) were enumerated in five random microscopic fields. The number of clusters per field is plotted against the number of cells per cluster for each cell line and treatment. ca-Akt, constitutively active Akt; IgG, immunoglobulin; OPN, osteopontin. (B) FSK-7 cells were transfected with either vector plus vector (V + V), constitutively active Akt plus vector, or constitutively active Akt plus antisense to osteopontin. Cells (5 × 10^4/60-mm-diameter dish) were grown in soft agar for 21 days. Micrographs were taken at a high magnification. Clone formation and clone size were enumerated in five random microscopic fields. (C) MT2994 cells transfected with either vector plus vector, dominant-negative Akt plus vector, or dominant-negative Akt plus osteopontin. CA-Akt, constitutively active Akt; dnAkt, dominant-negative Akt; V, vector; OPN, osteopontin; AS-OPN, antisense osteopontin. Error bars, standard errors. *, P < 0.1; **, P < 0.05; ***, P < 0.01.

transduced with vector constructs did not form clones in soft agar (Fig. 6B). In a complementary approach, expression of dominant-negative Akt in MT2994 cells caused a partial reduction in the numbers and sizes of clones formed (a shift of the histogram to the left), consistent with the partial suppression of Akt kinase activity by the dominant-negative construct. Coexpression of osteopontin virtually completely reversed this inhibition (Fig. 6C). The differences among the transduced MT2994 cells did not reach statistical significance, which is likely due to the incomplete suppression of endogenous Akt activity by the dominant-negative construct. Dominant-negative variants of essential growth-promoting gene products can typically be overexpressed only at moderate levels (1). Residual Akt activity has previously been observed after transfection with the Akt (K179M) construct (12, 32).

We tested in vivo tumorigenesis and dissemination by using doubly transduced FSK-7 cells. As expected, cells transduced with vector plus vector or with vector plus antisense osteopontin generated small hyperplastic lesions. In contrast, cells expressing constitutively active Akt generated larger tumors. Only the FSK-7 cells containing Akt plus vector, not the FSK-7 cells expressing Akt plus antisense osteopontin, formed distal lesions (Fig. 7). These experiments were extended to 30 days (at that time point, equal numbers of MT2994 cells are lethal), and the distal foci formed were smaller than those observed with MT2994, suggesting that additional factors may contribute to MT2994 malignancy. However, the observations are consistent with a critical role of Akt kinase in tumor growth and dissemination, the latter being mediated by high constitutive levels of osteopontin.

**DISCUSSION**

The molecular processes that lead to dysregulated growth of cancer cells can be distinguished from the molecular mechanisms that mediate dissemination. Osteopontin mRNA expres-
FIG. 7. In vivo growth and dissemination are mediated by Akt kinase and osteopontin. FSK-7 cells were doubly transduced, and 10⁶ cells were injected orthotopically into the left inguinal mammary fat pads of BALB/c mice. One group of five mice received either FSK-7 cells transduced with vector plus vector or FSK-7 cells transduced with vector plus antisense osteopontin (as-OPN), five mice were injected with FSK-7 cells transduced with constitutionally activated Akt (CA-AKT) plus vector, and five mice were given FSK-7 cells transduced with constitutionally activated Akt plus antisense osteopontin. After 30 days, the mice were analyzed for tumor formation and metastasis. Primary tumors are shown at the top, and metastases detected during necropsy are shown at the bottom.

...tion and secretion by ras-transformed NIH 3T3 cells correlate with these cells' levels of ras expression and their metastatic ability (9, 10). In contrast, LTA cells transfected with ras or with ras plus v-myc decrease the expression of osteopontin and remain tumorigenic but nonmetastatic (13, 14, 37). Osteopontin is the physiologic ligand of CD44v6, which also mediates dissemination without altering tumor growth. Expression of the CD44 splice form containing the variant exon 6 on various tumor cells is necessary and sufficient to mediate metastasis formation. Overexpression of CD44v6 in nonmetastasizing pancreatic tumor cells was sufficient to establish full metastatic behavior (22). In a complementary approach, a monoclonal antibody to the metastasis-specific exon of CD44 retarded lymph node and lung colonization by a metastatic pancreas tumor line (44). In mice that are susceptible to carcinogenesis due to p53 mutation, the absence of the CD44 gene leads to abolishment of osteosarcoma metastasis but not to changes in tumor incidence or growth (54). Based on the phenotypes of mice with knockouts of various confirmed metastasis genes, including osteopontin and CD44, the genetic basis of metastasis formation has been identified as aberrant expression or splicing of a unique set of developmentally nonessential genes that physiologically mediate the homing of immune system cells (53).

Metastasis formation arises with consistent patterns of organ preference. It has not been clear how the primary defect of growth dysregulation is linked to the expression of specific metastasis genes. We have screened signal transduction molecules associated with the EGFR receptor and have identified constitutive phosphorylation, indicative of activation, of Akt kinase in malignant, but not in benign growth-dysregulated, immortal breast epithelial cells. Akt kinase activity supports tumor growth as well as the induction of osteopontin, a metastasis gene that is essential for breast cancer dissemination to bone. Our results may provide a molecular explanation for the previous observation that transfection of Akt1 into immortalized, not fully transformed Comma-1D cells mediates, mutually independently, the transformation and invasion of breast epithelial cells (40). Human breast carcinogenesis is associated with a loss of cellular retinal-binding protein (CRBP) expression in about one-fourth of all cases. The inhibition of the PI 3-kinase/Akt kinase pathway by CRBP suppresses breast cancer cell survival and anchorage-independent growth (30). The latter is likely due to the inhibition of osteopontin gene expression. Elevated Akt kinase activity is also seen in metastasizing, but not in nonmetastasizing, liver tumor cells (36). Akt kinase has also been associated with the invasiveness of pancreas cancer, but here the pro-metastatic gene induced by Akt is the IGF-I receptor (48).

The cause for the constitutive activation of Akt kinase in MTT2994 cells remains unknown. Activating mutations in Akt itself seem unlikely, because mutants with known activating amino acid changes, such as E40K, still respond to inhibition by wortmannin. The loss of negative regulators of Akt kinase may desensitize the enzyme and generate the appearance of PI 3-kinase independence. We have sequenced the mRNA of PTEN, the most prominent negative regulator of Akt, in MTT2994 cells and FSK-7 cells (data not shown). No mutations were found in either case. Reduced expression levels of PTEN or a lack of other negative regulators are likely causes.

Our studies of murine transformed breast epithelial cells have indicated that constitutive activation of Akt kinase, independent of PI 3-kinase, causes a malignant phenotype through continuing cell cycle progression and expression of osteopontin (MT2994 cells). In contrast, breast epithelial cells may be immortalized through signal transduction that is independent of the EGF/PLC/PI 3-kinase/Akt kinase pathway (Comma-D cells and FSK-7 cells), but this transformation is not associated with osteopontin gene expression or with metastasis. Dysregulation of Akt kinase activity also plays a prominent role in...
human breast tumor cells. There, the constitutive activation of Akt kinase is typically secondary to overexpression of ErbB on the cell surface and is dependent on PI 3-kinase. Estrogen stimulates Akt activation, which is reflected in phosphorylation at serine 473 of the oncoprotein, in estrogen receptor-negative breast cancer cells. Activation of Akt by estrogen in these cells is time and dose dependent and can be blocked by inhibitors of PI 3-kinase and Src kinase but not by estrogen antagonists (49). The interdependent regulation between the estrogen receptor α and PI 3-kinase/Akt pathways may play an important role in human breast carcinogenesis and could contribute to ligand-independent breast cancer cell growth (46). Here we describe a single molecular defect responsible for both growth dysregulation and induction of metastatic potential in breast cancer cells. It enhances our molecular insights into carcinogenesis and defines candidate targets for therapeutic intervention.

KEY WORDS. Osteopontin, Akt kinase, breast cancer, signal transduction, gene expression, soft agar

INTRODUCTION. Two hallmarks of malignant tumors are uncontrolled growth and dissemination to selected target organs. In contrast, benign tumors also grow excessively, but do not express the gene products necessary for homing and invasion. This suggests the existence of two forms of defects in growth control pathways: benign tumors may be caused by mutations that solely induce growth promotion and immortalization, while gain-of-function mutations of oncogenes or loss-of-function mutations of tumor suppressor genes underlying malignant tumors promote cell cycle progression and immortalization, as well as the expression of metastasis genes. The molecular basis for this convergence between two apparently independent signal transduction cascades has not been identified.

We have defined metastasis genes as stress response genes that are dysregulated in cancer by aberrant expression or splicing. Here we analyze signal transduction mechanisms that connect proliferation and induction of the metastasis gene osteopontin in malignant breast tumors.

HYPOTHESIS. We hypothesized that, in malignant breast cancer, gain-of-function mutations in EGF-mediated signal transduction pathways lead to overexpression of the osteopontin gene. In benign breast tumors, by contrast, the signal transduction events that lead to excessive growth do not activate osteopontin expression.

In epithelial cancers, excessive growth is often secondary to dysregulation of epidermal growth factor–associated signaling pathways. Intracellular signal transduction associated with members of the EGF receptor family is mediated by multiple proto-oncogenes, including protein kinase C, phosphatidylinositol 3-kinase, and Akt kinase. Overexpression of Her-2/neu leads to constitutive activation of phosphatidylinositol 3-kinase and Akt kinase.

Cancer metastasis frequently depends on the expression of the cytokine osteopontin. Induction of osteopontin has been shown to be sufficient for metastasis formation by mammary epithelial cells[1–3]. Transfection of cells with osteopontin increases their malignant phenotype[4], while transfection with antisense oligonucleotides yields populations with reduced malignant potential[5,6].
EXPERIMENTAL METHODS. We have studied signal transduction and cell physiology in murine benign and malignant breast epithelial cell lines by application of chemical inhibitors and transfection of Akt kinase constructs. We have supplemented osteopontin or neutralizing antosteopontin antibody. Soft agar colony formation correlates well with the capacity of tumor cells for invasiveness in vivo. We tested the importance of Akt kinase and osteopontin for dissemination of breast cancer cells in soft agar colony formation. We used four murine Balb/c breast tumor cell lines with various levels of malignancy. Comma-D cells are derived from culture of mid-pregnancy mammary glands and develop hyperplasia when injected into mice. FSK-7 cells were obtained from primary breast cell culture. TM2H cells are a derivative of FSK-7 cells after loss of p53 and transformation; they form lesions in vivo after injection. MT2994 cells were derived from mammary tumors that had been induced by DMBA. Among these cells, only MT2994, and to a lesser extent TM2H, are malignant in vivo. Even though these cell lines were derived from various mice at various time points, their shared inbred genomic background of Balb/c mice allows them to be viewed as a progression series of breast tumor cell lines.

RESULTS. Osteopontin gene expression is inducible by growth factors in benign cell lines and constitutive in malignant cell lines (Fig. 1). These results were confirmed by RNAse protection assays and Western blotting. We analyzed the dependence of osteopontin expression on signal transduction events associated with epidermal growth factor stimulation. The constitutive expression of osteopontin is insensitive to inhibition of phospholipase C or phosphatidylinositol 3-kinase and is associated with constitutive activation of Akt kinase (protein kinase B).

FIGURE 1. Osteopontin expression in transformed breast epithelial cells. Comma-D cells and MT2994 cells were grown on cover slips in the presence or absence of growth factors. The cells were stained with fluorescently labeled antibodies to actin (top row, FITC, green) or osteopontin (bottom row, phycoerythrin, red). Nuclei were stained with DAPI (middle row, blue). No nonspecific signal was detected after incubation with streptavidin-phycoerythrin, in the absence of antiosteopontin antibody. Likewise, a nonspecific FITC-labeled antibody did not visibly stain the cells (not shown).
We further tested the contributions by Akt kinase to cell growth and induction of osteopontin. Akt transfection into benign cells mediates constitutive osteopontin expression, whereas expression of a dominant negative Akt kinase mutant in malignant cells suppresses the osteopontin levels. Akt kinase overexpression renders the breast tumor cells capable of forming clones in soft agar. This is partially inhibited by antosteopontin antibody. Suppression of Akt kinase activity by a dominant negative mutant suppresses the ability of clone formation. The supplementation of purified osteopontin can partially relieve this (Fig. 2).

**FIGURE 2.** Soft agar growth by breast tumor cells in dependence on Akt kinase and osteopontin. The benign FSK-7 cells were transfected with vector or a constitutively active Akt kinase (myrAkt). Their soft agar growth was assessed in the presence or absence of antosteopontin antibody or control IgG. The malignant MT2994 cells were transfected with vector or a dominant negative Akt kinase. Their soft agar growth was assessed in the presence or absence of osteopontin or bovine serum albumin (BSA) control. After 3 weeks, number and size of cell clusters per high powered microscopic field were enumerated. The bars represent the average of 5 fields.

**CONCLUSIONS.** Our experiments have identified Akt kinase as a candidate signal transduction molecule to mediate the connection between epidermal growth factor–induced signaling for cell cycle progression and induction of the metastasis gene osteopontin. Constitutive activation of Akt kinase correlates with growth and malignant potential. The identification of a single defined defect in growth factor signal transduction that also induces metastasis genes enhances our molecular insights into carcinogenesis and it defines candidate targets for therapeutic intervention.

**ACKNOWLEDGEMENTS.** This study was supported by National Institutes of Health research grant CA76176 and Department of Defense breast cancer grant DAMD17-98-1-8060 to GFW. Dr. Joseph Jerry kindly provided the breast tumor cell lines. The Akt kinase constructs were a generous gift of Dr. Thomas Franke. This paper was presented at the Third International Conference on Osteopontin, San Antonio, TX, May 10–12, 2002.
