MOST COMPUTER SYSTEMS: SHIPYARD APPLICATIONS

Louis Kuh
H. B. Maynard and Company Inc
Stanford, Connecticut

ABSTRACT

An overview of the Most Computer System is presented, as it may best be applied in the shipyard, including the structure of time data for shipyard use. The simplicity and ease of preparing methods improvements with the computer aided materials are outlined, and finally, examples from shipyard applications are reviewed.
One of the basic needs in the shipbuilding industry is to know the true work content for each ship --- preferably in advance. Because of the "one of a kind" nature of shipbuilding, time study was considered to be useless as a general tool for defining work content in advance of construction. Predetermined time data - as it became available - provided the opportunity to define work content in advance of manufacture -- but the number of analyst hours required to define each hour of work was so high, that it was still considered impractical or uneconomical to use the systems. Nevertheless, the basic need for measure of true work content - as opposed to historical data - remained.

The use of predetermined time data to build standard data through tables and formulas was a further step towards reducing analyst time, and the fact that many basic operations were repetitive (such as the welding of panels) helped to reduce again the analytical time -- but it was considered to be too high.

The development of the Maynard operation sequence technique (MOST) brought us a work measurement technique that was specifically designed to accomodate long-cycle, non-repetitive types of work. When MOST was combined with the work management manual approach to recording and reporting data, it began to be feasible to measure the work content of the shipbuilding process. However, there were still two tasks that involved a considerable amount of manual effort: searching the files for existing reusable data, and totalling the "bits" of time into the large number of hours required for segments of a ship.
MOST Computer Systems has finally brought us to the stage of development that reduces the manual efforts of recall and summation -- plus! We believe that today we have a well defined work measurement system that is practical and economical for shipbuilding purposes.

SNAME Panel SP-8 on Industrial Engineering has provided the impetus and support necessary to implement MOST Computer Systems. As a result, we are getting the hands on experience needed to prove the value of MOST Computer Systems in the shipyard.

Incidentally, some of you who have had exposure to the Japanese shipbuilding techniques may feel that the industrial engineering program is extraneous -- since the successful Japanese Yards do not have an I.E. function. At this POI presentation, I will point out the fallacies in that evaluation.

MOST COMPUTER SYSTEMS - AN OVERVIEW

Last year at the IREAPS Conference, Maynard gave a detailed review of MOST and we will not attempt to go over all that ground today. In a quick review, MOST uses a family of six descriptive sequences to define manual operations, the use of tools, and the use of cranes and trucks for material handling. By using specific key words and a well defined sentence structure, a computer program has been prepared that permits an analyst to "write" the method as it is performed in a defined work area. The computer applies the proper sequence and the time values to the written method steps.
Before describing the basic procedure, let’s look at the total program package that makes MOST Computer Systems.

There are five basic system programs and six supplementary modules programs that may be combined to provide the most usable system for a given situation. The programs are:

A. Basic Programs

1. MOST Analysis - The preparation of work area layouts and the methods description.
2. Suboperations Data Base - A file of completed method descriptions in suboperation and/or combined suboperation form.
3. Time Standard - The preparation of actual labor standards.
4. Standard Data Base - Same function as suboperations data base, except that complete standards are filed.
5. Mass Update - A program that permits overall modification of the time standards for the change of a common factor.

B. Supplementary Modules

1. Machining Data - The preparation of machining process times.
2. Welding Data - The preparation of welding process times.
3. Line Balancing - For complex assembly line operations.
4. Multi-man Machine Analyses - For making the best use of labor resources.
5. Word Processing - A program used for text and form preparation. A version of the program is specifically designed to prepare work management manuals.

THE MOST PROGRAM

The MOST program itself is, of course, the basic tool for time standard preparation. The program consists of two specific parts.

A. The work area layout, and
B. The method description.

The work area layout is a simple block diagram of the work area involved. Within the work area, we define workplaces (each location where work is performed such as a work bench, a machine, a storage rack, a space on the platen, etc.) and the things we find at the workplaces - such as the operator, pallets, tools, the objects we will be working with, and the equipment. Finally, we define the physical relationships or distances between each workplace. Figure 1 is an example of a work area in a fabrication shop where we will be bending brackets.

With the work area coded and defined, we are ready to write the method for a job in that area. Each method or suboperation is first coded and titled in accordance with a set of rules that has been established to simplify recall and future use of the suboperation.

Figure 2 is an example of a method for bending brackets in the work area illustrated in Figure 1. The program incorporates a tracking system that simplifies the way we describe a method step, and the operator, the objects and the tools are automatically traced from one workplace to another - or from a workplace to an operator or vice versa.

Total TMU 4010.
If it is desirable to review the feasibility of a work area arrangement, you have the flexibility of editing an existing work area by changing distances, or workplace locations, or by adding tools, etc. You may then use the same method steps and get the new or revised time frame without having to rewrite the method, or you may edit the method description for the same effect. You have a simple tool for testing and evaluating methods changes without the manual effort of rewriting and preparing hard copy.

If the work area has been properly defined, you may associate almost any number of suboperations with a given work area.

The end result of the MOST program then, is a number of work area layouts, with the associated methods descriptions or suboperations. Naturally, it is most desirable to define a suboperation as a unit of work that is repetitive in nature so that you may take the maximum advantage of the filing system described next.

THE DATA BASE

Once the analyst - or user - has created a work area and a suboperation, the next step is to file the completed work in a permanent file where it can be readily accessed. That file is the data base. A suboperation like "place tube in bender" will be the same for many sizes of tubing, and for almost any subsequent bending operation. When we have the suboperation in the data base, we want to be able to recall it at any time we may need it.
By using a well defined title procedure for each suboperation, with a restricted and defined word list for title components, we are able to create a search routine that will enable us to recall any filed suboperation.

There are ten basic components to the title structure -- as follows:

1. **ACTIVITY** - A verb that describes the overall action being carried out, such as: BEND, BURN, or WELD.

2. **OBJECT/ASSEMBLY/COMPONENT** - A noun that describes the item receiving the action - such as: Bend TUBE, burn LIGHTENER HOLE, or weld STIFFENER.

3. "IN", "ON" "FOR" - You select the appropriate preposition.

4. **PRODUCT/EQUIPMENT/ASSEMBLY** - The item that the object is a part of, such as: bend tube for BOILER, burn lightener hole in WEB, or weld stiffener on DECK PANEL.

5. "WITH"

6. **TOOL** - The actual tool being used to accomplish the activity: bend tube for boiler with BENDER, burn lightener hole in web with TRACER BURNER, or weld stiffener on deck panel with MIG.

7. "AT" , "TO" - You select the appropriate word.

8. **SIZE/CAPACITY/TYP**E - A modifier for the next segment: Bend tube for boiler with bender at #875...
   Burn lightener hole in web with tracer burner at OPTICAL...
   Weld stiffener on deck panel with mig at #1...
9. ORIGIN - Specifies the work area or machine where the work is done:
   bend tube for boiler with bender at 3875 GREENLEE...
   burn lightener hole in web with tracer burner at optical BURNER...
   weld stiffener on deck panel with mig at #1 WELD STATION...

10. MACHINE # OR WORK PLACE # - Specification of the exact machine or location involved:
    bend tube for boiler with bender at #875 greenlee SHOP70
    burn lightener hole in web with tracer burner at optical burner HARDINGE.
    weld stiffener on deck panel with mig at #1 weld station PLATEN 2.

An individual designated as the data coordinator is assigned the task of filing each suboperation in the data base. He does not review the analyst's work, but does review the suggested title for completeness and accuracy. He files the suboperation in the data base after making sure that the title is correct and complete, and that the suboperation is not a duplication of something already in the data base. The computer will automatically assign a sequential locator number for use in future recall actions.

Once filed in the data base, the suboperation is available to all users. A user may search the data base by part or all of the title, and will be able to review some number of suboperation from which he may then select the one he can use, or can modify for use. He will copy the selected suboperation on his own file (electronically) and there he may edit it or modify it as required.
Combined suboperations may be created and filed in the data base by making combinations of suboperations that are involved in the manufacture of some end product.

We now have a data base that is a source of material for the time standard program, or for the development of additional suboperations.

**TIME STANDARD**

A time standard is normally made up of a number of suboperations or combined suboperations, which may have different frequencies of occurrence, each of which is then modified by allowances for personal time, unavoidable delays, and human fatigue (usually referred to as P, F, & D) as well as an efficiency factor for a process time.

The time standard program is initiated with a header sheet that has a number of filing categories - similar to and for the same basic purpose as the titles in the data base program - and any other pertinent identifying or reference information. We then enter all the appropriate suboperation and/or combined suboperation locator numbers involved in the product, together with the proper frequency of occurrence for each one. The program will then prepare:

1. **A METHOD INSTRUCTION** - A step by step description of the work by suboperation title.

2. **A TIME CALCULATION** - A list of the steps in the standard, the frequency of occurrence assigned, the step time and the total time.

409
3. A RATE SHEET - A list of external manual times, internal times, and process times, showing the allowance percent, the allowance time, the standard time for each, the total standard time, the pieces per cycle, and the standard hours per piece.

The ability to produce those output documents makes the time standard program invaluable. We no longer need to have a large number of clerks turning out paper - nor do we need to maintain large file drawers full or records and documents. We can call up any of the documents we need in seconds -- and produce whatever hard copy we need at that time.

Another feature is the editing capability, which permits us to modify any individual standard as we make methods improvements or other changes. Engineering changes may be readily incorporated.

MASS UPDATE

The mass update program is another major convenience. Any time we find it necessary to change an element or suboperation that is common to many standards, or to change some assigned allowance, it would be laborious to make those changes either manually or one standard at a time. The mass update program allows us to identify the element to be changed, identify all the affected standards, and to make the change in all the standards simultaneously.
WORD PROCESSING

The word processing program has the added advantage of a special version specifically designed to produce the work management manual. It will not only produce the needed text material, but can literally pull any needed material from other MOST Computer Systems files for direct inclusion in the manual, without the need of retyping the data.

As with any word processing program, it has the basic advantage of permitting rapid editing and constant updating to provide real-time MOST Computer Systems documentation.

THE MACHINING DATA PROGRAM

The machining data program calculates process times for machining operations and documents the feeds and speeds for operator instructions. These values are to be used in conjunction with manual times and allowances in the time standards program to set standards for machine shop operations. (Figure 3)

The program determines the ideal speeds and feeds by using values recommended in the machining data file. The program selects feeds and speeds after considering the material used, tool, machine specifications, dimensions of raw and finished workpiece, etc. When the ideal speeds and feeds are not available due to machine limitations, the program allows you to select alternative speeds and feeds. This is an automatic procedure when the machine specifications have been included in the data file. The machining operations included in the program are drilling & milling and turning (single point tool).

- **Feed Rate Selected**: 5,0000 (Set 5,0000)
THE WELDING PROGRAM

The welding program contains four basic files: joint descriptions, electrode descriptions or specifications, the welding method or procedure, and the manual elements involved. We enter the appropriate information in each file that is associated with our operation. Examples from each file are found in Figures 4 and 5.

In order to create a welding process time, we only need to identify the joint code, and the method code (the method specifies the electrode). The program then processes the information in its files to calculate the arc time (Figure 6) and the manual time. The result is reported out in a format that may be converted into a suboperation and placed in the data base.

Both the machining data program and the welding program are options in the sense that even without them, the analyst can determine process time by a manual formula, and enter those times in a suboperation, or directly in the time standard.

The creation of most suboperations with the computer programs is, initially, slightly less time-consuming than with the manual methods. However, as the data base is built up, more and more reference to existing suboperations will reduce the need for creating new method descriptions from scratch.

415
Beyond the initial data preparation, the computer system is unequalled in terms of its ability to create time standards and the needed documentation for implementation. The facility for maintaining up-to-date data, making revisions, and accessing the files is far superior to any manual system of filing or using the data.

To accommodate the special needs of the shipbuilding industry -- with its large products encompassing many thousands of manhours -- there are a few enhancements to the programs that are either in place, in process, or planned. Briefly these include:
A. **Time Standard Summary** - This feature is presently included in the software. Given specific ship component coding, it is possible to request a list of all standards on file that pertain to a given piece of work (a hull section, a deckhouse, or even the whole ship). The result is a title listing of all the standards involved, a statement of the number of standards involved, and the total standard hours for the defined work. In other words, a summary time for any specified code or construction level of the ship.

B. **Real Time Work Standards** - This enhancement is planned, and involves the modification of a given time standard for real time planning purposes - and/or for estimating.

Since the shipbuilding industry has not traditionally used engineered time standards, we must carefully define the level of application to be used, and the method of using the standards. First we must realize that the time standard produced through MOST Computer Systems is a labor standard. This standard defines the time required to accomplish a defined piece of work when the operator is working at the 100% performance level, and when there are no unavoidable delays or non-work events.

C. **Maxi MOST** - For measuring large scale fabrication and assembly operations.
PRACTICAL APPLICATIONS OF MOST

Whether we want to modify the labor standard for performance or other factors, depends directly on the way we intend to use the standard. We need to identify the various areas of application for time standards. The following lists include most of the applications, divided in three basic shipyard functions.

1. INDUSTRIAL/ MANUFACTURING/ PRODUCTION ENGINEERING
   a. Methods Improvement
   b. Tool, Equipment and Machinery Evaluation
   c. Facility Layout, Flow and Workplace Arrangement
   d. Productivity Improvement Through Delay Identification and Elimination
   e. Manning - Balancing and Critical Path Determination
   f. Labor Incentives
   g. Make/Buy Analyses
   h. Long Range Facilities Planning

2. PRODUCTION
   a. Supervisory Control
   b. Manpower Distribution and Assignment
   c. Labor Performance Reporting and Analysis
   d. Productivity Improvement

3. PRODUCTION PLANNING, SCHEDULING AND CONTROL
   a. Labor Budgeting
   b. Shop Scheduling
   c. Critical Path Development
d. Material Requirements Planning (when and where)
e. Estimating

Now let's take a look at the various outputs of MOST Computer Systems - and see where they are used in the application areas.

1. MOST Program -
   Work area layouts. The defined work area incorporating the space, workplaces, objects, tools, equipment and carriers used to perform specific work.
   Method steps. The exact description of an element of work in the work area.

   These outputs can be directly used for applications la, lb, and lc.

2. The Data Base program -
   o Suboperations. A group of method steps required to complete a specific task or operation at a work area.
   o Combined Suboperations. A group of suboperations required to produce a specific component, subassembly, assembly or product.
   o Process Time. The time required for a machine or process monitored by an operator. This calculation is usually determined by time study or from special tables or from the welding and machining programs.

   These outputs can be directly used for applications la, lb, lc, le, and lg.
3. The Time Standard Program -

Time Standards. Combined suboperation and appropriate process time(s) plus allowances for personal time \( P = \) washroom, coffee break, etc.) human fatigue \( F = \) unavoidable delay \( D = \) Foreman instructions, multi-operator interaction, safety meetings, etc.) and process efficiency (e.g., machine operating variations, welding process modifications, etc.). The time standard defines the time required to perform a predetermined amount of work at the 100% performance level.

These outputs can be directly used for applications (1) all, and (2) all.

4. Application Standards -

A modification of a time standard to account for real world situations. Application standards are derived by applying temporary (revisable) allowances to time standards. The temporary allowances account for such events as crane or material handling delays, material shortage delays, crew imbalances, actual labor performance (i.e., performance will improve from 20% to 60% over the first five ships of a class) and "uncertainty" factors for estimating purposes. (Uncertainty factors would include evaluations of increases or decreases in work content of a new ship in comparison to a ship for which there are existing standards, and expected patterns of material flow, etc.)
These application standards are used for applications 1d, 1e, 1h, 2b, 2c, 2d, and 3 all.

We are now considering an enhancement to the time standard program to permit a second level (or even a third level) of time standards -- the application standard -- to be developed within the program by using appropriate allowances. The proper application of the mass update program will permit us to maintain the application allowances at whatever real world state we wish. Under any circumstances, we must use these allowances manually in order to arrive at standards that are usable by the planning and control functions of the shipyard.

5. An enhancement in the process of being finalized (and it is really a further development of MOST Systems) is Maxi MOST.

In spite of the fact that MOST Systems of standards development gives us the ability to produce valid standards for long cycle and non-repetitive operations with a minimum investment in analyst time, there is always the call for something even faster. It is not unexpected that members of the shipbuilding industry are in the vanguard of those companies seeking such a goal.

Toward that end, H.B. Maynard and Company has been working with two clients to develop an advanced version of MOST for use in "heavy" industry. One client is a manufacturer of large trucks, and the other is a shipyard.
The system is called Maxi MOST, and utilizes five basic sequences: three for manual activities, and two for material handling. In Maxi MOST, the index values are ten times larger than those used for Basic MOST. Thus implying that each method step in Maxi MOST would cover ten times the work as each step of Basic MOST -- and thus be ten times faster to apply. It is probably more realistic to say that the application speed of Maxi MOST is about five times faster than that of Basic MOST.

The system itself has been developed and applied manually for about six months, and has been fairly well debugged. At this point in time, the computer version has been developed, and testing was initiated just over two weeks ago. It is anticipated that the computer module for Maxi MOST will be fully debugged and ready for general use before the end of this year.

During the debugging period, evaluations are being made to define the levels of accuracy that can be expected -- relative to the work cycle time and the balancing time of the system. There is no doubt in our mind that Maxi MOST has great potential in the majority of shipyard construction and erection operations.

In summation, MOST Computer Systems is a powerful tool for the shipyard -- one that enables us to set engineered time standards for any yard.
operation rapidly and accurately. The use of the computer enables us to file, review, adjust, and synthesize a vast amount of data within a short time period - and with relatively little manpower. It provides the ability to produce updated and effective end use documents on command. Finally, it provides a solid basis for linkage to an overall management information system. It provides the essential element of sound labor reporting, evaluation and control that has the major impact on shipyard cost.

With reference to the Japanese success story, they are in fact using most of the classical I.E. functions, such as: methods improvement, development of special jigs and fixtures, process flow improvement, production standards development, and line balancing. The work is being done through the services of "Production Engineers" assigned to each major area of the shipyard -- men with degrees in naval architecture or engineering.

Further, the Japanese have had the advantage of building large numbers of similar type ships. One result is that they have been able to refine their "historical" standards and key them to such parameters as total weld length, feet of pipe, and total weight. Since those parameters have some significance on similar ships, they have also developed the special factors and allowances reflected in their operations -- and they use those predetermined standards for planning, estimating, budgeting, etc.
The MOST Computer Systems programs that we have described give us in the United States the opportunity to develop predetermined standards specifically designed for the onesy-twosey type of operations that dominates our shipbuilding. It also provides a much more effective means of identifying those nonproductive operations and those delays that we can exert effort to eliminate, and make radical improvements in our productivity.

As a result, we are getting the hands on experience needed to prove the value of MOST Computer Systems in the shipyard. Through the SNAME SF-8 Panel Industrial Engineering Program the potential uses of MOST Computer Systems in the shipyard are being tested and applied. By the end of the current program year, it is expected that the data development and program refinement work will be complete. There will be sufficient data to validate the expectations, and to define the planned applications of labor standards in shipyard operations for next year's program.
