Abstract

Defence Research and Development Canada (DRDC) – Valcartier, with the support of the CRAC Laboratory at École Polytechnique de Montréal, carried out an ambitious R&D project aiming at developing a tool called SOCLE which integrates the design of software applications with their security. Integrating the design of software applications and security into a unique tool is not only particularly innovative but also crucial to ensure the quality and security of critical command and control information systems. Moreover, as it is 50 to 100 times more expensive to correct a software error once the design phase is finished, detecting and correcting errors at design-time saves time and money. This paper presents the SOCLE project’s major achievements along with a simplified case study on Caveats, as an illustrative example of a possible military application for this new technology.

1. Introduction

It is now generally recognized that the design phase is crucial to the development of high-quality software. Nowadays, software is omnipresent and its faults can involve enormous social and economic repercussions. Sad examples abound: the Therac-25 radiotherapy machine (3 dead and 3 severely wounded persons), the ARIANE 5 rocket (approximately 500 million US dollars loss), the breakdown of AT&T network (approximately 60 million US dollars loss), etc.1 However, programs’ behavior is generally only validated after their partial or complete implementation, using various testing techniques. Moreover, it is estimated that correcting a software error after its implementation is 50 to 100 times more expensive than at design-time [2]. Thus, there is a real need for design-time validation techniques.

With this objective in mind, Defence Research and Development Canada (DRDC) – Valcartier initiated a project to develop a tool that allows the integration of security within the design of software applications. The idea is an innovative exploitation of constraints in Unified Modeling Language (UML) diagrams. These security constraints are expressed in the Object Constraint Language (OCL), hence the name Secure OCL expressions (SOCLe). The UML notation is currently the de facto industrial standard for the design of object-oriented, modern software. Indeed, it is used to support software engineering best practices. With UML, it is possible to specify the structural and behavioral aspects of software using standardized diagrams. OCL is integrated into the UML standard and expresses class invariants and pre/post-conditions on operations. These constraints specify and clarify the meaning of UML diagrams by precisely describing the correct model behavior.

The SOCLE project is carried out by a team of student members of the Conception et Réalisation des Applications Complexes (CRAC) Laboratory at École Polytechnique de Montréal, and is directed by professor John Mullins. It tackles the important problem of design-time validation. In

Standard Form 298 (Rev. 8-98)  
Prescribed by ANSI Std Z39-18
the first research phase, the SOCLe team compiled an exhaustive state-of-the-art study in order to judiciously choose technologies to be used throughout the project. UML was essentially selected because of its popularity in the industry. OCL is interesting for several reasons: it is integrated into the UML standard, it is easy to use, and, especially, it is possible to give it a precise and unambiguous meaning and to integrate it into rigorous verification techniques. Research efforts continued thereafter with the formal design necessary for the implementation of the SOCLe tool. This implementation phase initially targeted the development of an automatic verification engine, and then the design of a graphical user interface for this engine. Considerable efforts were also invested in order to improve the engine’s performance, which is now adequate.

The rest of this paper is structured as follows. Section 2 discusses similar tools found in the literature. Section 3 presents the general architecture of the SOCLe tool. Section 4 details the simplified case study used throughout this paper: a caveat-separation system. Sections 5, 6, and 7 sketch the utilization of the tool using this case study. Finally, Section 8 presents ongoing improvements to the tool and conclusions. Note that some familiarity with UML and OCL is assumed. The reader is referred to [10] for an introduction to UML. Details about OCL can be found in [9].

2. Related Work

Few research tools are currently available for static and/or dynamic validation of UML diagrams. Lilis and Paltor [8] propose vUML, a tool that translates UML statechart diagrams into Promela, the modeling language of the SPIN model-checker. Constraints are expressed through Linear Temporal Logic (LTL) and are transmitted to SPIN. Similarly, Latella et al. [7] give a provably-correct translation from a subset of UML statechart diagrams into Promela. None of these approaches, however, have taken OCL into account.

The toolset proposed by Shen et al. [11] offers static and dynamic validation. Static checks include: syntactic correctness according to well-formedness constraints of the UML meta-model, coherence of an object diagram with respect to a class diagram, and validation of OCL constraints on an object diagram. The dynamic checks consist of the verification of statechart diagrams using the SMV model-checker. However, OCL constraints are not considered by this model-checker either. Therefore, they are not supported as a dynamic constraint specification language.

Extensions for OCL constraints are suggested by Distefano et al. [5], using Computational Tree Logic (CTL), and Bradfield et al. [3], using propositional $\mu$-calculus. The general idea is to replace the atomic properties of these temporal logics by standard OCL constraints. Note, however, that neither of these frameworks support UML as a design notation.

3. SOCLe Architecture

SOCLe is divided into three main modules:

1. a UML compiler,
2. a specialized Abstract State Machine (ASM) interpreter [1], and
3. a model-checker (Figure 1).²

The tool works with UML diagrams expressed in the XML Metadata Interchange (XMI) format, which is supported by most UML CASE tools. The verification process has three phases:

1. translate the UML diagrams into an ASM executable specification,
2. simulate the execution of the generated specification, and
3. verify OCL constraints against the resulting execution graph.

The UML compiler translates UML diagrams to an ASM according to a formally-defined semantics. Basic diagram elements, such as classes and method names, are mapped to sorts (data domains). More complex elements, such as method declarations and statechart transitions, are translated into enumerated functions. The object diagram is mapped to a specific subset of these functions and represents the initial configuration of the UML diagrams.

The ASM interpreter simulates the execution of the ASM specification. From an initial configuration, successor configurations are computed by evaluating an ASM program capturing the dynamic behavior of the UML diagrams.

The model-checker verifies the OCL constraints by translating them into a set of properties and applying a verification algorithm [4]. The result is transmitted back to the graphical user interface through a set of diagnostic files.

SOCLe includes a graphical user interface embedded into argoUML, a customizable open-source UML CASE tool³. It allows the designer to visualize verification results and to inspect the diagrams’ execution graph.

²For the sake of brevity and to respect the scope of this paper, no technical details are given about the ASM formalism and model-checking techniques.
4. Caveat-Separation System: Simplified Case Study Specifications

The main objective of the case study is relatively simple: design and verify a simplified caveat-separation system based on the following specifications.

4.1. Users

Of course, a caveat-separation system implies the management of users. In this system, users have the following attributes:

- A country of origin. For example: “Canada”, “US”, “UK”, “Germany”, or “Egypt”.
- A military rank: “General”, “Officer”, or “Civilian”.

Except for the country of origin, these attributes can be modified in time. For instance, one particular user can be upgraded from “civilian” to “officer” or from “secret” to “top secret”. It is infrequent for a military rank to be downgraded but the system should handle this situation for the sake of completeness. For example, a retired military officer working as a contractor could be classified civilian for caveat-evaluation purposes.

4.2. Documents

In this caveat-separation system, users want to access documents. Documents have the following attributes:

- A classification level: “Unclassified”, “Confidential”, “Secret”, or “Top Secret”.
- A caveat. For example: “CEO”, “CANUS”, “CANUSUK”, “NATO”, “UN Coalition”, or “USUK”.
- An affiliation with a project. For example: “Project A”, “Project B”, or “Project C”.

Here, all attributes can be modified during the lifespan of a document, even though certain modifications are unlikely to happen.

4.3. Access Control Tables

There are three access control tables that dictate who can access which documents: the classification table (Table 1), the caveat table (Table 2), and the need-to-know table (Table 3). They are all presented in the following subsections.

4.3.1 Classification Table

Table 1 presents the access relation between the security clearance of users and the classification level of documents. Of course, the higher the classification level of a document, the higher the security clearance required to access it. This
4.3.2 Caveat Table

In Table 2, the caveat of the document dictates acceptable countries of origin for the user who wants to access it. This table is simply an example. Of course, many other caveats and countries exist. However, for the purpose of the current caveat-separation system, it can be considered to be fixed.

4.3.3 Need-to-Know Table

Table 3 determines who, in terms of countries of origin and military ranks, has the “need-to-know” in order to access the documents of a particular project. A user must not only have the proper security clearance and country of origin to be able to access a document but must also have what is called the “need-to-know”. In this caveat-separation system, it is assumed that this “need-to-know” is attributed on a per-project basis and is related to a user’s country of origin and military rank. This table is simply an example and should not be considered fixed once and for all in the caveat-separation system. Indeed, new projects could be created, old projects could be terminated, and entries could be modified or deleted in time.

4.4. Property to Verify

Finally, the following property must be verified to be valid in the design of the current caveat-separation system:

At all times, a user can access a document if and only if the access is granted with respect to the classification, caveat, and need-to-know tables.

This is particularly essential if the attributes and/or the need-to-know table are dynamically modified.

5. Caveat-Separation System: UML Design

For any given design in SOCLE, the designer must include exactly one class diagram, one statechart diagram for each class defined in the class diagram, and one object diagram. In this section, these diagrams are illustrated through the modeling of the case study.

### Table 6. Caveat Encoding

5.2. Statechart Diagrams

Statechart diagrams are used to define the dynamic behavior of each object in the system. Figures 3 and 4 show the statechart diagrams of the *Sender* and *Controller* classes, respectively. Every class must have its statechart in order for SOCLE to be able to predict its dynamic behavior. For the sake of brevity, however, all the statecharts are not presented in this paper.

Notice that the control flow of a statechart is specified by states and transitions. The basic condition for a transition to be fired is that its source state is active. Accordingly, the basic response to firing a transition is the activation of its target state. In the case of composite states, the initial states they encompass are also activated. This basic statechart semantics is adapted from Harel’s statecharts [6].

In addition, transitions are labeled with a trigger, a guard, and a list of actions. Triggers refer to signals (atomic events), method calls, or method returns. For example, the list of actions of a transition labeled with trigger `inc` (for incrementation) will execute that method’s instructions. Guards are boolean OCL constraints. OCL constraints are presented in Section 6. SOCLE supports the following actions: method call/return, field assignment, object creation/deletion, and signal emission.

5.3. Object Diagram

The object diagram is used to define the initial state of all objects in the system. In other words, it gives the initial configuration of the system. Figure 5 shows a possible...
Figure 2. UML Class Diagram of the Caveat-Separation System

6. OCL Constraints

The syntax of an OCL constraint $c$ is defined as follows:

$$ c ::= v | x | △c | c_1 △ c_2 | c.f | c_1.iterate(x_1; x_2 = c_2|c_3) $$

It includes a significant fragment of OCL constraints as defined in [9]. Symbols $v$ and $x$ denote values and variables, respectively. Values include booleans, integers, object names, and lists. Construct $△c$ $(c_1 △ c_2)$ stands for the application of any of the usual unary (binary) operators on booleans, integers, and lists. Construct $c.f$ returns the value that field $f$ takes in the object $c$. The semantics of these constructs is formally defined as follows:

$$ [v]_{\rho} = v $$
$$ [x]_{\rho} = \rho(x) $$
$$ [△c]_{\rho} = △[c]_{\rho} $$
$$ [c_1 △ c_2]_{\rho} = [c_1]_{\rho} △ [c_2]_{\rho} $$
$$ [c_1.f]_{\rho} = heap([c_1]_{\rho}, f) $$

The application $\rho(x)$ retrieves the value of variable $x$ in the variable environment $\rho$. The application $heap([c_1]_{\rho}, f)$

object diagram for the caveat-separation system.

This diagram models a system composed of a user who can send a document to another user via a controller. Using Tables 1, 2, and 3, the latter determines if the receiver can have access to the document.
fetches the value of field $f$ according to the ASM function $heap$, defined by the UML compiler.

The iterate construct is OCL's main collection operator. Informally, it iterates variable $x_1$ through the values of the collection denoted by $c_1$, stores the successive values of $c_3$ in variable $x_2$ (which first evaluates to $c_2$), and returns the final value of $x_2$. The formal semantics of this construct is simply too complex for the scope of this paper. It is, however, quite expressive and this is why it is used to encode additional collection operators, that are supported by SOCLE. Figure 6 illustrates some of them.

7. Caveat-Separation System: An OCL Constraint

It is possible to give OCL constraints for each statechart of the system in order to validate each module separately but it is even more interesting to define global OCL constraints that validate the entire system as a whole. The OCL constraint defined in Figure 7 is a good example of such constraint. It ensures that the behavior of the controller is correct. Since the security of the whole system depends on the controller, its behavior must be validated. The constraint verifies the three conditions that must be valid prior to the execution of the operation $access(u: User, d: Document)$:

1. the security clearance of the user is higher or equal to the classification level of the document (1),
2. the nationality of the user is compatible with the caveat of the document (2), and
3. the military rank of the user is compatible with the document project (3) (modeling the need-to-know).

As shown in Figures 8, 9, 10, 11, 12, and 13, SOCLE can automatically verify this constraint for the entire system. This ensures the security of its design.

8. Conclusion and Future Work

This paper has presented a tool that integrates the design of software applications and their security by using OCL constraints on UML diagrams combined with innovative automatic verification techniques. Such a tool is of paramount importance for the design of critical military command and control information systems because these systems have to be not only robust but also secure. Moreover, the detection and correction of errors earlier in the development cycle saves time and money. Finally, a case study on a caveat-separation system has been presented in order to illustrate...
the capabilities of the SOCLE tool.

A few improvements are currently underway. They essentially consist in translating the UML diagrams into an intermediate control flow language before analyzing their behavior and using a local model-checking algorithm to drive the computation of a system’s execution graph. Such improvements will facilitate the implementation of various static analysis techniques such as slicing and code generation. They will also reduce memory requirements as some constraints could be falsified/verified even tough the execution graph is only partially computed.

Frédéric Painchaud
Defence Scientist
Trusted C2IS Group
High-Assurance Software: A Question of Correct Design

- Software abounds in mission-critical systems
  - Banks, hospitals, emergency services, public utilities, governments, military organizations, etc.
- High reliability and security requirements
  - But very complex and fragile
- Three main issues:
  - Design problems (system architecture)
  - Implementation problems (programming languages and platforms used)
  - Malicious code (viruses, trojans, worms, backdoors, etc.)
- Correcting errors during or after implementation is costly
  - 50 to 100 times more expensive than at design-time

Validating Design: Our Key Approach

- Integrate design and system specification
- Use an innovative mix of UML and OCL
UML and OCL

- UML is the *de facto* standard software design notation
  - Used in the industry and in C2IS and other governmental critical systems
- OCL is a complementary constraint language
  - Eliminates ambiguities in software design
  - Formulates pre-/post-conditions and invariants
  - Part of UML

UML: Unified Modeling Language
OCL: Object Constraint Language

Plan of the Presentation

1. SOCLe Architecture
2. Caveat-Separation System: A Simplified Case Study
3. SOCLe Prototype
4. Conclusion
Conclusion

• Critical software design should be and can be formally verified to some extent
• Reduces the risk of design problems and defects in the implementation
• Error detected
  – Falsified property when the access rules for documents can be updated while the point-to-point transfer is still in progress.
• Reasonably scalable
  – But state explosion on large systems
• Work in progress
  – State reduction techniques
  – On-the-fly validation
Conclusion

- Technical reports
  - Caveat Case Study
  - An ASM Semantics of UML and OCL
  - Java Source Code Generation from UML
  - etc.
- Quebec Provincial FIQ OCTAS 2005 Winner
  - Finalist in the Canadian CIPA Awards
- IBM Canada at Ottawa is particularly interested in SOCLe technology transfer
  - Inline with their current vision
  - PolyMTL is currently preparing a proposition for IBM on how to integrate this technology into their tools
