<b>14. ABSTRACT</b>  The Army's One Semi-Automated Forces (OneSAF) Objective System (OOS) is a composable, next-generation computer generated forces (CGF) that has been designed to represent a full range of operations, systems, and control processes from the entity level to brigade level. Its development has leveraged the ever-increasing computing power available today to represent highly-complex battlefield phenomena, particularly entity and unit behaviors.  In the fall of 2005, the Product Manager (PM) OneSAF asked the United States (US) Army Training and Doctrine Command (TRADOC) Analysis Center (TRAC) in Monterey, California (TRAC-MTRY), to develop and execute quantitative and qualitative tests to verify the orderable, composite behaviors within OOS. As a result, we developed and executed a unique process to verify those behaviors under tight resource constraints. We developed an overall behavior verification methodology, a test design construct, a verification tracking database, and a detailed reporting procedure. We then executed the verification process on OOS behavior models and provided valuable feedback to PM OneSAF. Our methodology and test designs allowed us to evaluate the behaviors thoroughly with a minimum number of scenarios. Additionally, we devised a process to verify traceability within the documentation from requirements to implementation. Our work led to a follow-on effort to automate the verification process for OOS.

## **Acknowledgements**

There are a number of individuals who contributed to this project. We would like to thank some of them here by name. In particular, we thank Mr. Harold Yamauchi and Ms. Jane Wu, from Rolands and Associates Corporation, who were the ‘boots on the ground’ executors of the verification methodology. They executed the test designs in the One Semi-Automated Forces (OneSAF) Objective System (OOS) for each behavior and recorded the results in the tracking spreadsheets. Their efforts were essential to the success of this project. We would also like to thank MAJ Joseph Nolan, who started on the project at its initiation. His efforts were instrumental in the development of the initial verification methodology that was subsequently refined and finalized.

Additionally, we thank Dr. Robin Rose, Ms. Denise Ball, and Mr. Damon Baker, from the United States (US) Army Training and Doctrine Command (TRADOC) Analysis Center at White Sands Missile Range, NM (TRAC-WSMR), for their insights into conducting verification of the OOS primitive behaviors and their input into our processes and efforts. From the US Army Materiel Systems Analysis Activity (AMSAA), we thank Mr. Andrew Barnett, who provided useful insights into AMSAA’s processes for verifying the OOS physical models.

Finally, we thank the PM OneSAF team for their support, interaction, and timely feedback to our questions. Specifically, we recognize then-LTC John Surdu (PM OneSAF), Ms. Ha Ly, Mr. Clark Karr, Mr. Michael Fernandez, Mr. James O’Neal, and Mr. David Nash. They responded quickly to our questions and were always willing to provide assistance with the model and its documentation, despite their busy schedules.

## **Executive Summary**

The Army's One Semi-Automated Forces (OneSAF) Objective System (OOS) is a composable, next-generation computer generated forces (CGF) that has been designed to represent a full range of operations, systems, and control processes from the entity level to brigade level. Its development has leveraged the ever-increasing computing power available today to represent highly-complex battlefield phenomena, particularly entity and unit behaviors.

In the fall of 2005, the Product Manager (PM) OneSAF (then-LTC John Surdu) asked the US Army Training and Doctrine Command (TRADOC) Analysis Center (TRAC) in Monterey, California (TRAC-MTRY), to develop and execute quantitative and qualitative tests to verify the orderable, composite behaviors within OOS. As a result, we developed and executed a unique process to verify those behaviors under tight resource constraints. We developed an overall behavior verification methodology, a test design construct, a verification tracking database, and a detailed reporting procedure. We then executed the verification process on OOS behavior models and provided valuable feedback to PM OneSAF. Our methodology and test designs allowed us to evaluate the behaviors thoroughly with a minimum number of scenarios. Additionally, we devised a process to verify traceability within the documentation from requirements to implementation. Our work led to a follow-on effort to automate the verification process for OOS.

As the Army's simulation of choice for brigade-and-below operations, the use of OOS throughout the Army will continue to increase. Since OOS is designed to support all Army modeling and simulation (M&S) communities, its impact on the warfighter cannot be overstated and will directly affect the equipment, support, and training warfighters receive. Ensuring that the behavior representations within OOS execute properly, the focus of this study, is essential to the successful implementation of the system.

The methodology and tools developed as part of this effort have a number of desirable characteristics. First, they are interoperable, both within the Army and across Joint M&S. The methodology and tools are not specific to OOS and can be used to facilitate the verification of behaviors within simulations throughout the Department of Defense. By design, the methodology and tools are reusable for behavior representations within any model or simulation.

Our effort was innovative and advanced the state-of-the-art for verification and behavior modeling. While there is a large compendium of best-practices for verification, there was not

anything specific for the application to behavior modeling, a relatively new concept in simulation development. Thus, a unique methodology had to be developed to meet this niche need.

Finally, our effort saved, and can continue to save, government resources. First, our process demonstrated sound behavior test designs using a minimum number of scenarios, thus saving both time and money. Additionally, our work facilitated improvements to OOS early in its development lifecycle that would be much more costly if done later. Feedback from PM OneSAF and others involved throughout the course of the project praised this work for providing a clear path forward, saving time and manpower, and providing useful insights into improving OOS.

## Section 1 – Introduction

### 1.1. Overview

The One Semi-Automated Forces (OneSAF) Objective System (OOS) is the first set of simulation products to be developed through the formalized Army acquisition process. Randolph and Sagan (2003) provide a concise general description of OOS in the following quote.

*OneSAF is a next-generation Computer Generated Force (CGF) that can represent a full range of operations, systems, and control processes from individual combatant level and platform level to fully automated BLUFOR battalion level and fully automated OPFOR [opposing forces] brigade level. OneSAF is not a single product or system, but rather, a set of products each consisting of a set of interacting components and tools. These components provide overlapping functionalities, which meet the various Object Oriented System (OOS) compositions. They also interact with data and meta-data housed in repositories. (p. 6)*

At the initiation of this research effort, the OOS main development phase was drawing to a close with the program preparing for project release. Prior to its release, the program was required to pass the government acceptance testing (GAT), scheduled for summer, 2006. In October, 2005, in advance of the GAT, LTC John Surdu, PM OneSAF, requested that the US Army Training and Doctrine Command (TRADOC) Analysis Center in Monterey, CA (TRAC-MTRY), develop and execute quantitative and qualitative test designs to verify that the orderable composite behavior models in OOS performed according to their design specifications.

In this report, we begin with a description of the problem background, including a general overview of the OOS model with focus on its behavior modeling functionality; more detail concerning our problem scope; and a summary of related efforts. The subsequent portion of the report will lay out the methodology we developed to conduct our verification and will include examples. We then briefly describe our general results and the challenges we faced. At the conclusion of the report, we describe the direction of our continued work and conclude with a summary of our efforts.

## 1.2. Problem Statement

One of the unique aspects of OOS is its behavior models. Although the behavior model functionality is designed to allow the user to develop his own behaviors as necessary, the OOS development team created a set of 51 orderable composite behaviors representative of the most-likely tasks that a unit or entity might be required to perform within a normal mission. Our task was to evaluate and report on the performance of these composite behavior models. Initially, our guidance was to evaluate as many composite behaviors as possible in advance of the GAT, originally scheduled for January, 2006. With the postponement of the GAT, we were given an extension to continue work until June, 2006. Even with the extension, the timeline and our available resources severely constrained the scope of our research.

The PM OneSAF was asking us to conduct a *verification* of the composite behavior models. According to Department of the Army Pamphlet 5-11 (1999), verification is defined as “the process of determining that an M&S [model and simulation] accurately represents the developer’s conceptual description and specifications” (p. 7). Thus, we were not to conduct validation, which is “the process of determining the extent to which an M&S is an accurate representation of the real world from the perspective of the intended use of the M&S” (p. 7). As we will discuss later, making that distinction proved to be challenging when information about the behavior’s “conceptual description and specifications” was insufficient.

## 1.3. Problem Scope

### 1.3.1. Limitations

- TRAC-Monterey did not have enough resources to verify all 51 composite behaviors.
- Documentation of behavior implementation was incomplete, which limited our ability to determine with certainty the required behavior performance.
- For any given behavior, there were too many potential inputs to test each possible combination.
- The data collection functionality within OOS was not mature enough to collect all of the output data required.

### **1.3.2. Assumptions**

- Developing a behavior verification methodology and verifying a subset of the original 51 behaviors would provide value to the PM OneSAF team and the necessary foundation to continue behavior verification beyond our efforts.
- Documentation, in conjunction with OOS development team consultations, provided sufficient information to verify behavior performance.
- Testing a representative sample of scenarios for each composite behavior is sufficient to verify behavior performance.

**This page intentionally left blank.**

## Section 2 – Background

### 2.1. OOS Behavior Modeling Functionality

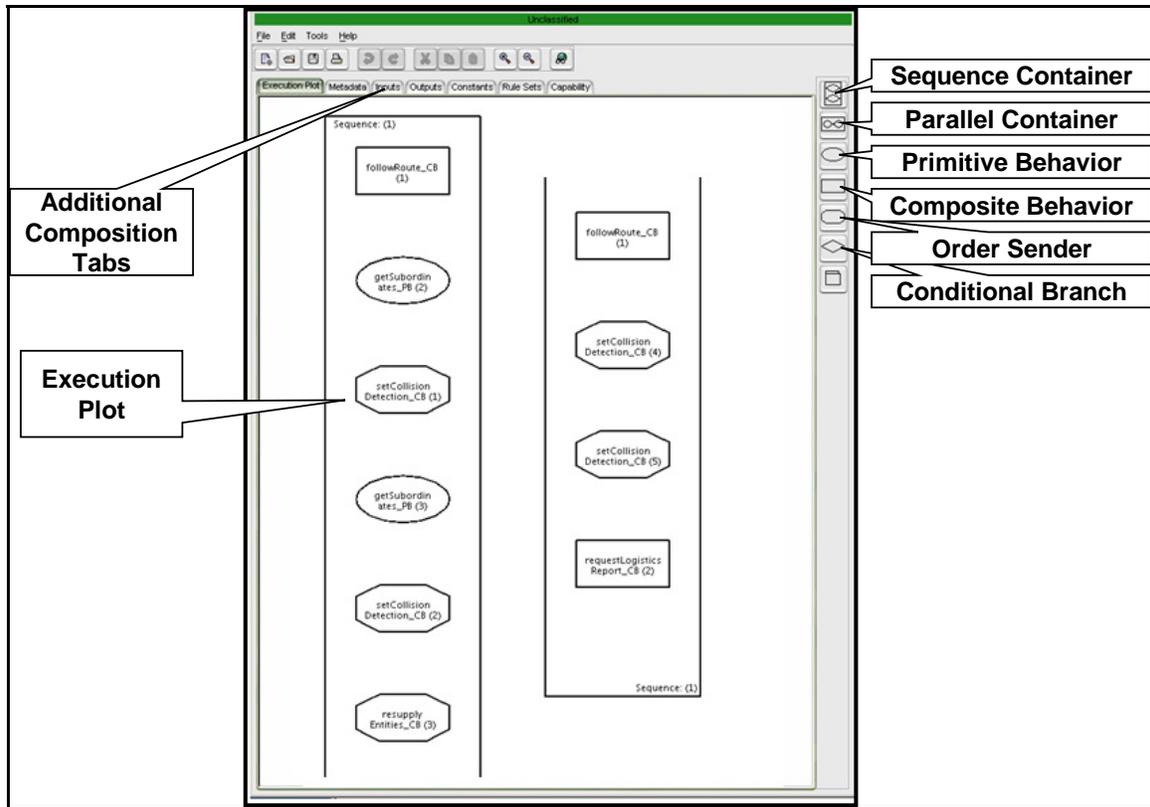

OOS behavior models implement typical decision processes used within a military framework, and thus “provide command and control of equipment and unit models during simulation execution” (Henderson & Granger, 2002, p. 1). Therefore, they provide a means to automate standardized decision processes in order to reduce or remove user input during simulation execution. The models are able to evaluate environmental and situational stimuli and cause the entities or units to react accordingly.

There are generally two main types of behavior models – primitive and composite. Henderson and Granger (2002) define primitive behaviors as “simple chunks of doctrinal functionality from which more complex behavior models are built” (p. 1). These are coded behavioral aspects that directly control the simulation’s physical models and agents. They define composite behaviors, on the other hand, as “complex behavior models and are composed of primitive behaviors and other composite behaviors” (p. 2). Composite behaviors are not code themselves, but “are defined in data files that conform to a [pre-defined] syntax” (p. 2). It is the *composite* behavior models that were the focus of this research.

The graphical user interface (GUI) that allows a user to develop composite behaviors is called the Behavior Composer Tool, shown in Figure 1. Henderson and Granger (2002) describe the Behavior Composer as:

*...a novel graphical user interface paradigm that enables users to construct composite behaviors by selecting composition elements from a toolbar, and then placing them on a drawing canvas. The Behavior Composer does not require the user to write source code or even understand the XML [extensible markup language] file format of the behavior descriptions it produces” (p. 7).*

While our research did not require actual behavior construction, we often explored the Behavior Composer to learn more about the intent behind the implementations of particular behaviors.

**Figure 1. OOS Behavior Composer Tool.**

Another aspect of the OOS behavior model implementation is the use of behavior models in the simulation. First, we must differentiate between orderable and reactive behaviors. Orderable behaviors are those behaviors that can be assigned to a unit or entity by the user during scenario development. A reactive behavior cannot be assigned, but can be enabled or disabled within an orderable behavior. Reactive behaviors define a standard reaction to particular stimuli (e.g., reacting to enemy fire). Because the occurrence of these situations cannot be predicted, reactive behaviors cannot be guaranteed to occur within a normal mission sequence, as orderable behaviors can. These two types of behaviors provide the capability to define the mission from start to finish, while still allowing simulation entities to react to unpredictable events.

When creating a scenario in OOS, the user assigns each unit a set of orderable behaviors by mission phase in the Mission Editor portion of the main interface, known as the plan view display (PVD), which is shown in Figure 2. When a behavior is assigned, the user edits its parameters through a set of GUIs, which will be discussed later in the report.

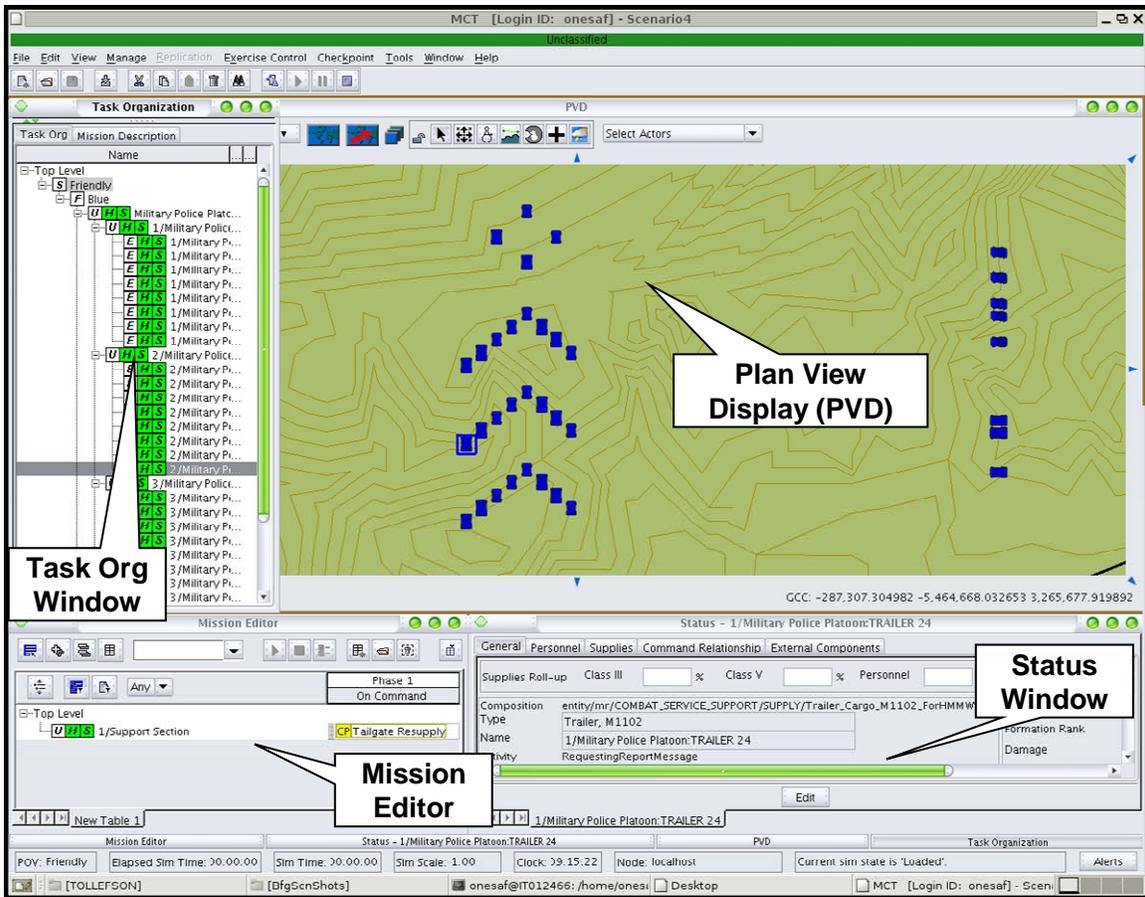

Figure 2. OOS Plan View Display (PVD).

## 2.2. Background Research

While previous combat simulations have had some behavior modeling capability, we could find no established verification processes specific to behavior models. Additionally, behavior model verification had not received the attention during OOS development that physical model verification had. In fact, only one other organization was working on a similar task. TRAC-White Sands Missile Range (TRAC-WSMR) initiated a primitive behavior model verification effort in late summer, 2005, at nearly the same time we had. Thus, our first step was to develop a methodology that we could use to conduct the verification. While there was little documentation concerning behavior model verification, we did find literature and previous research that addressed verification principles in general.

In October, 2005, an OOS development and training team traveled to our site to install the software and provide training. The training team brought with them a recommended approach for the verification effort that had been developed internally by PM OneSAF. Their

input was quite valuable for determining the types of information that would be most useful to their development effort and served as the foundation upon which we built our methodology.

Our second source of information was the *VV&A Recommended Practices Guide* (2000) downloaded from the Defense Modeling and Simulation Office (DMSO) website. The acronym VV&A stands for verification, validation, and accreditation. The guide describes the verification (and validation) processes and best practices from industry, the Department of Defense, and academia, with particular application to combat models and simulation. From this document, we were able to survey the large number of techniques available and extract those that were applicable to our work.

Our third reference was the *Models Development Behavior Verification Test Plan* (2004) developed by the Science Applications International Corporation (SAIC). Unfortunately, while the document did give a general framework for the conduct of verification, it provided little information concerning the methodology for selecting the test scenarios, nor what the outputs should be for each of the scenarios. In fact, when we tried to run these test scenarios and collect the data, we were not even able to load the files that were designed to be used in conjunction with the document. Additionally, the list of behaviors did not correspond to the list given to us by the OOS team, largely because the last update to the document occurred during the Block C release, not the Block D release we were testing initially. Therefore, while we did use the document to provide some information about potential testing scenarios, we based very little of our methodology on it.

Our fourth source of information was the work being done simultaneously by TRAC-WSMR. Their effort centered on the verification of the primitive behaviors, whereas our effort focused on the composite behaviors. Their selection of composite behaviors to execute in scenarios was based upon the primitives they contained, not the composite behaviors themselves. We referred to their methodology to make sure we accounted for overlapping aspects, and compared our results to identify significant differences; however, we were unable to base our methodology on theirs.

Finally, we consulted the US Army Materiel Studies Analysis Agency (AMSAA), which was simultaneously conducting verification of the *physical models* within OOS. While the focus of their effort was on an entirely different aspect of the simulation, their approach for selecting the design points in their test designs was valuable.

## Section 3 – Methodology

We developed a methodology that would ensure a thorough verification of the composite behavior models, while still allowing us to address as many behaviors as possible within our resource constraints. After our initial development of the methodology, we continued to refine its processes even after we had begun verifying individual behavior models. Nonetheless, the overall methodology remained unchanged and is shown in Figure 3.

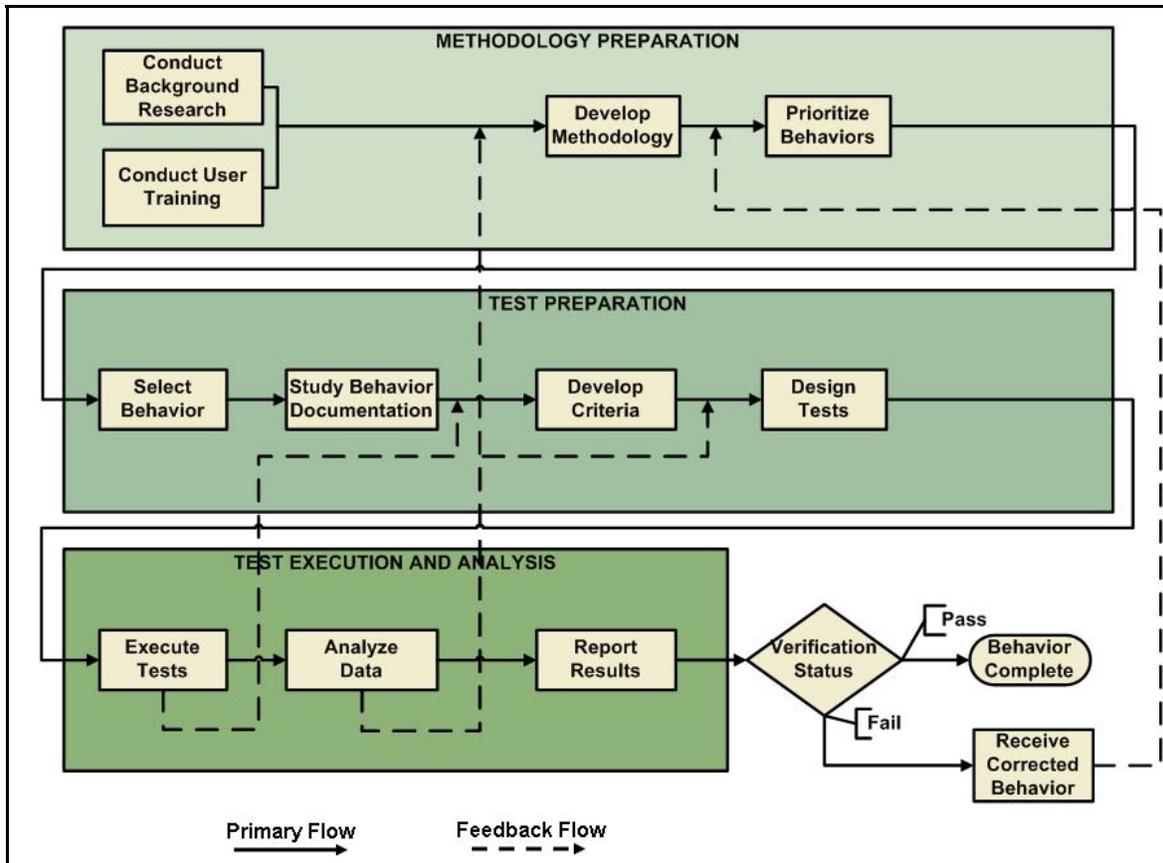

Figure 3. Behavior Model Verification Methodology.

### 3.1. Behavior Prioritization

Our first step was to prioritize the list of composite behaviors for verification and to update the list as required. The OOS team, during their onsite training visit, provided us an initial prioritized list of 51 composite behaviors, included in Appendix A, which served as our base document. The prioritized list did not change throughout the conduct of our research; however, we had to omit some behaviors whose documentation was not sufficient enough to conduct verification.

## **3.2. Behavior Selection and Documentation**

We selected a behavior from the prioritized list and then reviewed its source documentation. The documentation review was essential, since verification requires a complete understanding of the developer's conceptual description and specifications in order to evaluate its implementation.

### ***3.2.1. Documentation Description***

Our primary source of information was the behavior model documentation. The OOS developers created these documents as part of their knowledge acquisition / knowledge engineering (KAKE) process. Behavior model KAKE documents attempt to capture behaviors in terms of the problem space (the description of the real world) in a way that facilitates the conversion of reality into software models (the solution space). While it is beyond the scope of this report to describe the OOS KAKE process, we will briefly describe the key documents that were central to our research. The reader can find more information about the KAKE process in Randolph and Sagan (2003).

The primary problem-space documents were the Task Descriptions (TDs). These documents describe the Army Universal Task List (AUTL) tasks in a way that facilitates their representation in composite behavior models. The AUTL is a comprehensive list of tasks that the Army is required to perform in support of its mission. There is a one-to-one mapping of TDs to AUTL tasks, but not from composite behaviors to TDs. In other words, one cannot necessarily trace an implemented composite behavior in OOS directly to a single TD. The TD is a problem-space document, meaning that it attempts to describe actual behaviors in a detailed manner that can then be implemented in software. Therefore, it cannot serve as a primary reference document for verification because it does not necessarily match how the behaviors it supports are actually implemented. We did refer to the TDs occasionally to see if they could clarify gaps or misunderstandings encountered in the solution-space documentation, particularly in terms of nomenclature.

Another set of problem-space documents are the Process Step Descriptions (PSDs), which further decompose and describe component sub-tasks of the AUTL tasks. A single PSD may describe a sub-task which is shared by multiple AUTL tasks. Although the PSDs seem to represent the basic 'building blocks' of the AUTL tasks, there is no one-to-one mapping of PSDs to the OOS primitive behaviors, as might be expected.

The Behavior Process Documents (BPDs) represent the final set of problem-space documents. They describe real-world behaviors that may require representation as composite behaviors but have no associated AUTL tasks. Thus, they are used to fill the modeling gaps left by the AUTL. Again, these do not necessarily have a one-to-one correspondence with the implemented composite behaviors.

Modeling Notes are used by the software engineering team to record questions concerning the problem-space documentation and to request clarification from the behavior subject matter experts (SMEs). The answers are then recorded as well. This class of documents was sometimes useful for determining the intent behind the implementation of particular composite behaviors.

The primary solution-space documents are the Use Cases. These documents describe the actual implementation of the composite behaviors, and, thus, there is a one-to-one mapping of Use Cases to composite behaviors. Although titled “Use Case” on the actual documents, the OneSAF team often referred to them as “Design Documents,” which is more descriptive of their function. The Use Cases can be considered the “developer’s conceptual descriptions” of the composite behaviors and were thus the primary source of information for our verification efforts. They have as their sources the TDs, but may or may not reflect the same logic as that included in the TDs. Since there is not a one-to-one mapping of TDs to composite behaviors and their Use Cases, most Use Cases referred to numerous TDs. Unfortunately, the actual implementation of the composite behavior models was often not sufficiently documented in the Use Cases, which led to some significant challenges, which we will discuss later in the report.

### **3.2.2. Other Sources**

If the documentation failed to present a conceptual model complete enough to conduct verification, we consulted members of the OOS development team. If necessary, we were able to consult directly with the software engineer who implemented the behavior. We preferred to do this via email in order to maintain a written log of the questions we asked and the answers we received for future reference. Another source of information was our own expertise in Army operations and combat simulations; however, we had to be very careful not to make assumptions about how the behavior *should* perform, which is a validation issue.

### 3.3. Evaluation Criteria

Once we felt that we had a sufficient understanding of the intended implementation of the composite behavior model, we selected the criteria that we would use to evaluate performance. Throughout the following discussions, we will use the Tailgate Resupply composite behavior as our example to highlight the application of our methodology. In that behavior, the unit that is given the task, called the supplying unit, moves to a logistics release point (LRP – the location where the resupply operation will take place); supplies each of the designated vehicles there; and then moves to a return location (which is not necessarily its original location).

#### 3.3.1. Behavior Model Input Parameters

Before we discuss the actual selection of criteria, we first provide a brief overview of the behavior model parameter inputs. When a user assigns a composite behavior to a unit or entity, a dialogue window opens prompting the user to enter three types of parameters: required, optional, and rules of engagement (ROE). An example of the Tailgate Resupply behavior dialogue windows for each of the three types of parameters is shown in Figure 4.

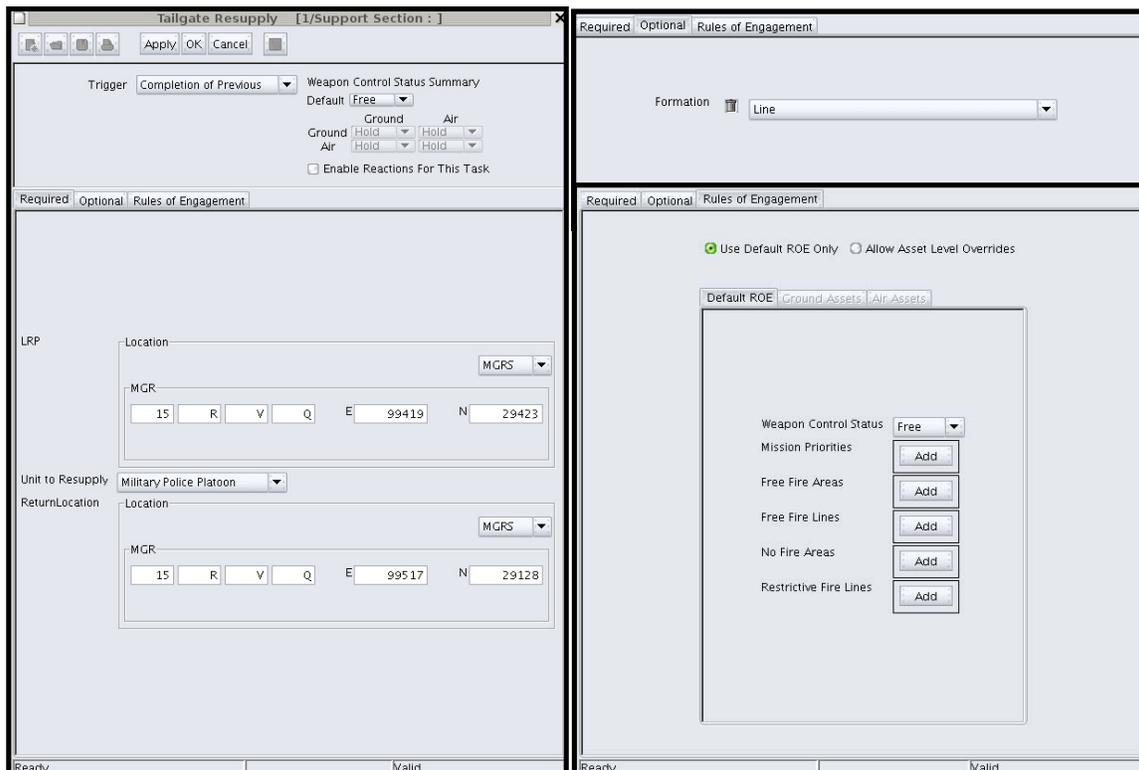

Figure 4. Example Behavior Input Parameter GUI for the Tailgate Resupply Behavior.

In our Tailgate Resupply example, the required inputs are the LRP location, the unit to resupply, and the return location. The only optional parameter is the formation in which the resupplying unit will move. The ROE parameters are identical for all behaviors and include settings for weapons control status (WCS), mission priorities, and fire control measures.

### **3.3.2. Criteria Selection**

To select the behavior evaluation criteria, we first looked to the input parameters. At a minimum, each input parameter was a criterion to be evaluated to ensure that the input value properly affected behavior execution. Thus, for the Tailgate Resupply behavior, we were interested in ensuring that the supply vehicles moved to proper location and in the correct formation, and that the proper units were resupplied (particularly in cases where multiple units are located in the vicinity of the LRP). Additionally, there were often other criteria that were not suggested by the inputs, but were still critical to evaluate. In our example, we were also interested in the amount of supplies delivered and received, as well as the time it took to execute the transfer.

To evaluate the criteria, we used both qualitative and quantitative measures. Many of our measures were qualitative for two reasons. The first is that the data collection functionality of the simulation (including basic data logging) did not work properly in the model releases we used. The second is that many of the criteria could be evaluated visually on the PVD during execution (e.g., the formation in which the unit moved). Despite the fact that the data collection functionality was not working, we were still able to collect quantitative data from the Status Window in the PVD (see Figure 2). The Status Window shows, for each unit or entity, nearly real-time information, such as speed, orientation, levels of supply, location, etc. Thus, we were able to pause the simulation at a point of interest and collect data from that window.

In the Tailgate Resupply behavior, we evaluated the following criteria visually: movement formation and movement to the correct locations. Quantitatively, we collected data on the types and amounts of supplies transferred, as well as the specific units and entities that participated in the operation. However, there was at least one criterion that we were unable to collect – the time it took to transfer supplies from one vehicle to another. This was a result of the fact that the Status Window had update delays that significantly impacted our ability to determine the relatively-short transfer times.

### 3.4. Test Design

To create our test design, we developed a set of scenarios that would evaluate the critical aspects of the behavior. Each scenario can be thought of as a single design point in the overall test design. The specific methodology for choosing the number of, and settings for, the scenarios varied by behavior, because the behaviors differed in complexity. For example, the Move Tactically behavior had 16 required and optional inputs. Those inputs aligned well with the critical aspects of the behavior that we wished to test. Tailgate Resupply, on the other hand, had only four required and optional inputs, but there were other aspects of the behavior that we wished to test that did not correspond to inputs. Thus, we had to take each behavior as a unique case and create the test design uniquely, instead of using a ‘cookie cutter’ approach.

#### 3.4.1. Conditions

The following is a general description of the types of conditions we tested.

**Inputs:** Since each parameter the user enters should have an effect on the performance, or output, of the behavior, we needed to test each unique setting for each input to ensure that the settings created the desired effects. We also had to test behavior performance in the absence of an input for the optional parameters. Additionally, there were other potential inputs that were independent of the behavior itself (e.g., unit type and echelon assigned the behavior). We needed to test a representative sample of those inputs as well. When determining the unit type and echelon, we ensured that they were varied between the scenarios, but did not try to test every possible input. For example, the Tailgate Resupply behavior can be assigned to any type of unit at any echelon (entity, team, squad, company, battalion, etc.). Testing all of those would be infeasible.

**Special Cases:** In addition to the inputs that the user can choose, we also wanted to test the robustness of the behavior. For this, we tested cases that would involve the behavior performing at the extremes or under unusual circumstances. For some behaviors, testing only the range of parameter inputs was sufficient; however, in most cases, we considered such additional aspects. Special cases in our Tailgate Resupply example included testing what would happen if the supply vehicles had the wrong supplies, had an excess or shortage of required supplies, had unnecessary supplies, or had to resupply multiple units. Additionally we wanted to test different classes of supplies (e.g., ammunition, fuel, medical supplies, etc.).

**Combinations:** Given the large number of potential inputs and variations the behavior could take, we did not try to test every possible combination of input parameters. For example, the Move Tactically behavior had 16 required and optional parameters, with some having as many as 13 choices, resulting in almost a million unique combinations of parameters. We instead tried to ensure that each critical aspect was tested at least once. For instance, if an input had seven potential unique settings, we would have at least seven scenarios. Thus, the parameter with the largest number of potential choices tended to drive the total number of scenarios. Since we were testing only a small subset of the possible combinations, we had to design each scenario carefully to ensure that each special case was tested as well. Consideration of special cases usually added one or two scenarios to the final number.

**Final Designs:** For each of the test designs, we kept the number of scenarios between six and ten. We found that range to be sufficient to test any of the behaviors we verified without taking an excessive amount of time. In some cases, we had to combine inputs. For instance, in the Move Tactically test, we only tested only one variation of each movement formation (e.g., echelon right but not echelon left). Our Tailgate Resupply behavior test design consisted of six scenarios. A portion of that test design is shown in Table 1. The columns represent each scenario and the rows represent each parameter or special case.

**Table 1. Example Behavior Test Design for Tailgate Resupply.**

SCENARIO #	1	2	3	4	5	6
<b>GENERAL SETTINGS</b>						
Resupply Unit Type	Armor	Infantry	Mech Infantry IFV	Military Police	Medical	Field Arty
Resupply Unit Echelon	Platoon	Fire Team	Platoon	Platoon	Section	Platoon
<b>SCENARIO CHARACTERISTICS</b>						
Classes of Supply Delivered	Class III and V	Class V	Class III	Class III & V	Class III & VIII	Classes III & V
Units Near the LRP	Multiple	Single	Multiple	Single	Multiple	Single
Units to be Resupplied	Single	Single	Single	Single	Multiple	Single
Level of Resupply	Subunit(s)	Unit(s)	Subunit(s)	Unit(s)	Unit(s)	Subunit(s)
Req'd Supplies Available?	Yes, all	Yes, some	None	Yes, some	Yes, all	Yes, all
Unreq'd Supplies Available?	Yes	Yes	Yes	No	No	No
Supply Amounts	Sufficient for All Types	Sufficient for All Types	Insufficient for All Types	Sufficient for Some Types	Sufficient for All Types	Sufficient for Some Types
Unit to Resupply	Section A, Armor Platoon 1	Fire Team	Section 2, Mechanized Infantry Platoon 1	Military Police Platoon	Medical Section to receive Class III and VIII. Transport Platoon to receive Class III only.	Section 2, Artillery Platoon
Formation	Vee	Wedge	Column	Line	EchelonLeft	EchelonRight

### **3.5. Test Execution and Analysis**

With the test design and evaluation criteria determined, we then set up the scenarios in the simulation. We attempted to keep the scenarios simple and to configure them in a way that would provide unambiguous results, instead of being concerned about tactical validity. In many cases, each composite behavior we tested required us to learn a particular functionality that we had not used previously. Thus, this initial portion of execution often consumed a significant amount of time. Often, we would identify conditions that were not, in fact, testable, leading to minor modifications of the design.

Once we created the scenarios, we simply observed and collected data. Sometimes, an interesting or ambiguous result would lead us to run additional excursions with minor variations to understand what was happening. As with scenario development, we sometimes encountered situations during execution that would lead us to alter the overall test design. While we usually ran each scenario numerous times to ensure that it was set up properly, we normally used only the data from the last run for reporting purposes, unless we noticed large variations in output during our trail runs. All behaviors we examined were deterministic, although the stochastic nature of other aspects of the model still caused variations in output between runs. The average time consumed by scenario development and execution was typically five to seven days.

### **3.6. Result Documentation**

Our primary concern in this verification effort was to ensure that we thoroughly recorded everything we did throughout the process, especially since our resource constraints limited the number of unique cases we could observe. We kept very detailed records in spreadsheet form that delineated our test design, the evaluation criteria, and results. As part of that, we often took screenshots of particularly interesting phenomena that would be difficult to explain otherwise. Additionally, we saved all of the scenario files we used, to include any excursions we ran, so that we could include those with our reports.

Our documentation consisted of two primary types of spreadsheets – an overall verification summary spreadsheet and a set of individual behavior verification spreadsheets (one per behavior). Each tab (worksheet) in the *verification summary spreadsheet* contains summary results from the verification of a particular behavior and includes details such as the overall assessment of the behavior, the summary results for each scenario, our references to

documentation, the particular OOS build we used in the verification, and other administrative details.

We recorded the detailed results for each behavior in the *individual behavior verification spreadsheets*. Each of these spreadsheets includes a series of worksheets, one per scenario in the test design. In each scenario worksheet, we recorded general descriptions of the scenario and the terrain, simulation entities and units involved, special cases examined, overall rating for the behavior in that scenario, and the detailed results for each evaluation criterion. Table 2 shows the portion of the worksheet we used to record the detailed results. The visual and data verification *plan* columns in that table identify the results we expected, and the visual and data *results* columns identify the actual results from scenario execution. In the status column, we recorded our assessment of the behavior model’s performance for each evaluation criterion (as green, amber, red, or unverified). We used the discussion column to provide additional detail about the results and our assessment.

**Table 2. Verification Collection Plan and Recording Spreadsheet.**

VERIFICATION PLAN & RESULTS		Visual Verification Plan	Visual Results	Data Verification Plan	Data Results	Status	Discussion
<b>TASK DIALOGUE SETTINGS</b>							
<b>REQUIRED PARAMETERS</b>							
LRP Location	See Scenario File						
Unit to Resupply	Section A, Armor Platoon 1						
Return Location	See Scenario File						
<b>OPTIONAL PARAMETERS</b>							
Formation	Vee						
<b>OTHER</b>							
Resupply Time	N/A						
Supplies Delivered	N/A						
Supplies Received	N/A						
Supply Accuracy	N/A						

The individual behavior verification spreadsheets also contained a summary worksheet that includes the overall results for each scenario. An excerpt from that spreadsheet was shown in Table 1, and the final versions of each summary worksheet are included in Appendix B. Each annex in that appendix represents a particular behavior. In Appendix C, we include the individual behavior verification spreadsheet for the Clear Room behavior, with each annex representing each of the scenarios in the test design.

After the completion of each behavior verification, we compiled the information collected in the spreadsheets, along with the scenario files, and sent them directly to the OOS development team. In addition to reporting the results of the behavior verification itself, we also

reported any documentation errors or shortcomings, as well as any general software performance issues we had encountered.

## Section 4 – Results

We must first note that the following results are specific to the particular versions of OOS that we used for the verification, many of which were developmental releases prior to the official release of the model. Thus, many of the problems found during the initial verification and re-verification processes have since been fixed in later releases. OOS developers were continually adding new functionality and making significant changes to the model during our verification process. The results shown in Table 3 should be understood within that context as a logical progression of the methodology we developed, and not the final stamp of pass/fail for the composite behavior model functionality within OOS.

**Table 3. Behavior Verification Test and Retest Results.**

<b>Behavior</b>	<b>Initial Test</b>	<b>Retest</b>
Move tactically	Red	Red
Tailgate re-supply	Green	N/A
Mount / dismount	Amber	Amber
Attack by fire	Amber	Red
Occupy position	Amber	Amber
Clear room	Red	Red
Tow to location	Red	Red
Conduct air reconnaissance	Red	Red
FWA platform follow route	Red	Amber
FWA unit follow route	Amber	Amber
Drop cargo	Red	N/A
Prepare for re-supply	Red	Red
Transfer cargo to basic load	Amber	N/A

Overall, we were able to conduct initial verification of 13 composite behaviors and retesting of ten. Each behavior verification test design included a number of scenarios that were evaluated based upon the developed criteria. For *each* of those criteria within the scenario, we assessed the behavior performance according to Table 4.

Each scenario was then assessed a green, amber, or red rating based upon a holistic view of the simulation’s performance with respect to the criteria. Similarly, the behavior itself was assessed an overall rating based upon its performance across the entire test design (all scenarios). Table 5 shows the rating schema at the scenario and behavior levels. In the table’s “description” field, the word to the left of the “/” applies to the evaluation of the *scenarios* and the word to the right of the “/” applies to the overall *behavior* evaluation.

**Table 4. Criterion Ratings.**

<b>Rating</b>	<b>Meaning</b>	<b>Description</b>
Green	Passed	Performed as expected
Amber	Unable to verify/ inconclusive	Performance could not be assessed, either because the data resolution was not fine enough to do so (making the results inconclusive), or because the documentation was unclear as to what exactly should occur
Red	Failed	Did not perform as expected
None	Unverified	No means to evaluate performance, due either to the failure of another criterion that altered behavior execution or to a deliberate choice to ignore the criterion based upon the conditions in the particular scenario

In the end, our assessments were necessarily subjective. Unlike physical models for which there is a defined set of parameters and performance expectations, composite behaviors involve sub-behaviors and other dependencies which prevent the development of concrete rule sets for ratings. However, we mitigated against such subjectivity by being meticulous in our recording of the precise observed performance for every criterion, scenario, and composite behavior. Thus, another individual or team could update the assessment based upon their interpretation of the significance of the resulting performance without having to re-run the model across the test design.

**Table 5. Scenario/Behavior Ratings.**

<b>Rating</b>	<b>Meaning</b>	<b>Description</b>
Green	Passed	Green for all criteria/scenarios, or primarily green for most criteria/scenarios with one or two amber ratings due to inconclusive data
Amber	Unable to verify/ inconclusive	Amber for a majority of the criteria/scenarios, or if there was mostly green ratings with one or two red ratings
Red	Failed	Failed one or more significant criteria/scenarios, or had one or more red ratings with a majority of amber ratings for the remainder of the criteria/scenarios
None	Unverified	No means to evaluate performance of the scenario/behavior

## Section 5 – Challenges.

### 5.1. Documentation

One of the primary challenges the team encountered during this process was insufficient or incorrect documentation, represented graphically in Figure 5. The fundamental shortcoming in the documentation was that there was no clear mapping between the problem-space and the solution space. Thus, when we encountered questions regarding the specifications in the Use Case, we could not refer to the problem-space documents to resolve them.

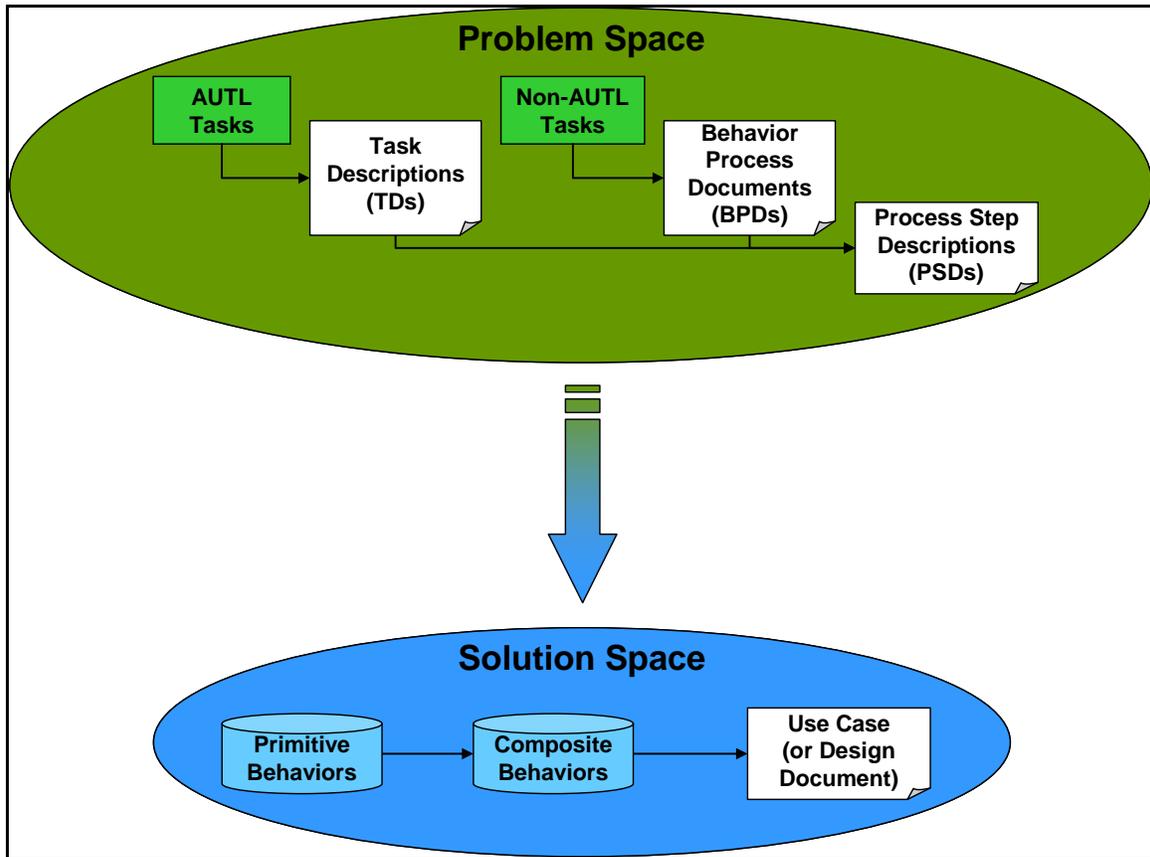

Figure 5. Figurative Representation of Documentation Deficiencies.

As we discussed previously, when we were unable to obtain the required information from the documentation, we sometimes had to rely upon our own operational expertise to understand what the model should do. However, we had to take great care not to draw conclusions about behavior performance based upon our assumptions. Thus, when a behavior failed to perform in accordance with our assumptions, we had to avoid using the following reasoning: “Based upon our experience (or our inferences about intent from XML or problem space documents), behavior X should do Y; thus, because it did not do Y, it fails.” When the

team encountered these situations, we made note of what we assumed should happen and what did happen and then labeled the behavior performance as “inconclusive” or “unable to verify”.

## **5.2. Data Collection Functionality**

The failure of the data collection functionality severely restricted our ability to collect quantitative data. While we were able to work around that by using the Status Window, the accuracy of our results was impacted. For instance, while location was reported in the Status Window, to verify the distance between two vehicles we would have to determine the location of the two vehicles in the Status Window and calculate the distance manually. However, because the distance may vary over time due to terrain, we needed an average of values, making the process very tedious. In some cases, such as supply transfer times in the Tailgate Resupply behavior, we were unable to collect the data at all.

## **5.3. Software Development Cycle**

Our final challenge had to do with the phase of the OOS software development in which we were working. In advance of the initial OOS release, the software developers were continuing to fix errors and add required functionality. However, the software still had bugs and inefficiencies that caused fairly frequent lock-ups or tedious work-arounds. Additionally, our sponsor, PM OneSAF, wanted us to conduct behavior model verification on the latest releases. Therefore, before we progressed to another behavior, we downloaded the newest release of the software, if one was available. Unfortunately, these releases sometimes had new functionalities or changes to the composite behaviors that were not reflected in the documentation. Thus, for each behavior, we had to check the software against the documentation before we got too far into our process.

## **5.4. Recommendations**

The following are some recommendations we developed to help alleviate the challenges we encountered during our efforts.

### **5.4.1. Documentation**

Software development must ensure a complete conceptual description of the behavior models. The implications of insufficient documentation extend beyond verification to validation and even to the users themselves, who must understand exactly how the behavior model will

respond to given set of inputs. Documentation standards must be developed early in the development process and adhered to throughout. The standards must address traceability from the real-world behavior itself through the final implementation, by ensuring that the documentation provides a clear link between the knowledge acquisition and engineering processes and the model implementation. While it is understandable that documentation may lag behind development to some degree, the program should take significant steps to ensure that traceability is maintained throughout, particularly before entering the verification stage.

#### **5.4.2. Data Collection**

A working data collection functionality is a requirement for verification. If the organic data collection functionality in the model is insufficient, the program should pursue external tools capable of collecting the required data. While significant strides can be made toward verification using other techniques, model generated data must be examined in order to truly verify many aspects of the implementation.

#### **5.4.3. Software Development Cycle**

Little can be done to prevent challenges resulting from multiple releases of the model; however, some techniques may mitigate the adverse impacts. First, the developers should ensure that any relevant changes to the behavior models being verified are documented, or at least noted, for the verification team. Second, they should ensure that the model release is stable before attempting to integrate it into the verification process. A third alternative is to choose a particular stable release of the model for a phase of the verification. Once the verification team is ready to begin retesting, a new release can then be used. The goal should be to minimize the model changes facing the verification team, instead of sending updated models as they are developed.

**This page intentionally left blank.**

## **Section 6 – Current and Future Efforts**

Following our initial behavior verification effort, TRAC-MTRY began to develop concepts and tools in order to automate portions of the behavior verification process, thereby significantly reducing time and manpower requirements. We used a spiral software engineering approach in the development of appropriate tools. The process involved additional background research, followed by a sequence of development phases. Each spiral iteration included problem definition, methodology review and update, and concept/software development.

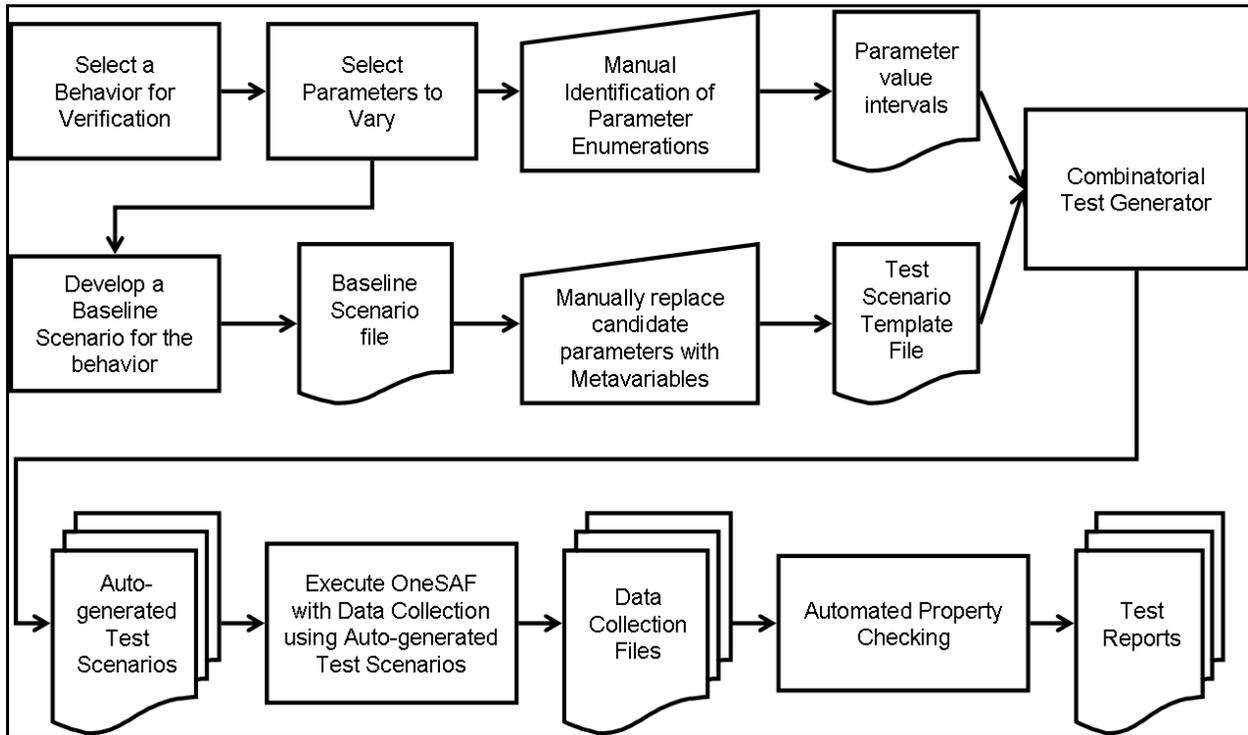

Development of automated behavior verification concepts and tools required a thorough understanding of the OOS software architecture. In order to automate the correlation between inputs and outputs, we needed access to internal software data structures and an understanding of the algorithms applied to the data. We focused our background research on those aspects.

The team then reviewed the generic requirements for verification, and re-evaluated our behavior verification methodology. Problem definition was a recurring part of the spiral development process, providing us the flexibility required in an open-ended research and development effort. Inputs into the problem definition process came from background research and previous tool iterations.

We successfully created a working prototype of the OneSAF Behavior Verification Automation tool. In its prototype form, the software developed auto-generates executable OOS scenarios and checks the output of the data files collected during the execution against pre-specified parameter characteristics. Figure 6 shows a flow chart representation of the prototype operation.

This prototype demonstrates the fundamental concepts which make the automation of behavior verification possible. TRAC-MTRY has been able to take a simple scenario; use it as a baseline scenario template; auto-generate varied test scenarios based on the baseline scenario; collect data in extensible markup language (XML) files using OOS' organic data collection tools; and conduct parameter checks to evaluate behavior performance using Ruby scripts. These scripts were capable of checking data files over 25 MB in size in less than five seconds. Future work focused on creating "linking software" which binds the significant pieces of software in this prototype together in a user-friendly manner. Future work also focused on developing a means of producing more significant parameter characteristic tests based on

expectations extracted from the developer’s documentation. The reader can find more details about this effort in a separate report to be published.

**Figure 6. Prototype Automated Behavior Verification Tool Flow Diagram for OOS.**

## **Section 7 – Conclusion**

We developed and executed a unique process to verify OOS composite behavior models under tight resource constraints. We developed an overall behavior verification methodology, a test design construct, a verification tracking database, and a detailed reporting procedure. We then executed the verification process on OOS behavior models and provided valuable feedback to PM OneSAF. Our methodology and test designs allowed us to evaluate the behaviors thoroughly with a minimum number of scenarios. Additionally, we devised a process to verify traceability within the documentation from requirements to implementation. Our work has led to a follow-on effort by TRAC-Monterey and the Naval Postgraduate School to automate the verification process for OOS.

As the Army's simulation of choice for brigade and below operations, the use of OOS throughout the Army will continue to increase. As OOS is designed to support all Army modeling and simulation (M&S) communities, its impact on the warfighter cannot be overstated and will directly affect the equipment, support, and training warfighters receive. Ensuring that the behavior representations within OOS execute properly, the focus of this study, is essential to the successful implementation of the system.

Our effort was innovative and advanced the state-of-the-art for verification and behavior modeling. While there is a large compendium of best-practices for verification, there was not anything specific for the application to behavior modeling, a relatively new concept in simulation development. Thus, a unique methodology had to be developed to meet this niche need.

Finally, our effort saved, and can continue to save, Army resources. First, our process demonstrated sound behavior test designs using a minimum number of scenarios, thus saving both time and money. Additionally, our work facilitated improvements to OOS early in the development lifecycle that would be much more costly if done later. Feedback from PM OneSAF and others involved throughout the course of the project praised this work for providing a clear path forward, saving time and manpower, and providing useful insights into improving OOS.

## Appendix A – Original Prioritized List of Composite Behaviors

**Table 6. Original Prioritized List of OOS Composite Behaviors for Verification.**

<b>Priority</b>	<b>Behavior</b>	<b>Priority</b>	<b>Behavior</b>
1	Move tactically	27	Provide treatment
2	Attack by fire	28	Cross level supply
3	Mount / dismount	29	Drop cargo
4	Tailgate resupply	30	Load/unload supply
5	Occupy position	31	FARP resupply
6	Clear room	32	Prepare for resupply
7	Send call for fire	33	Service station resupply
8	Move tactically (rotary wing aircraft)	34	Transfer cargo to basic load
9	Attack by fire (rotary wing aircraft)	35	Conduct capture rescue
10	Tow to location	36	Conduct interview
11	Attack built up area	37	Breach wall
12	Conduct raid	38	Clear and mark lane
13	Execute sniper mission	39	Construct HVIED
14	Conduct ambush	40	Construct obstacle
15	Conduct air reconnaissance	41	Cue radar
16	Conduct ground reconnaissance	42	Emplace bridge
17	Platform follow route (fixed wing aircraft)	43	Emplace minefield
18	Unit follow route (fixed wing aircraft)	44	Employ smoke
19	UAV conduct surveillance	45	Fire and relocate
20	Conduct repair	46	Hitch/unhitch
21	Conduct casualty movement	47	Maneuver and occupy fire support position
22	Conduct MEDEVAC	48	Perform river crossing
23	Conduct entity RWA MEDEVAC	49	Prepare fighting position
24	Conduct entity treatment	50	Retrieve bridge
25	Passage of lines forward	51	Withdraw
26	Passage of line rearward

## **Appendix C – Detailed Results for the Clear Room Behavior**

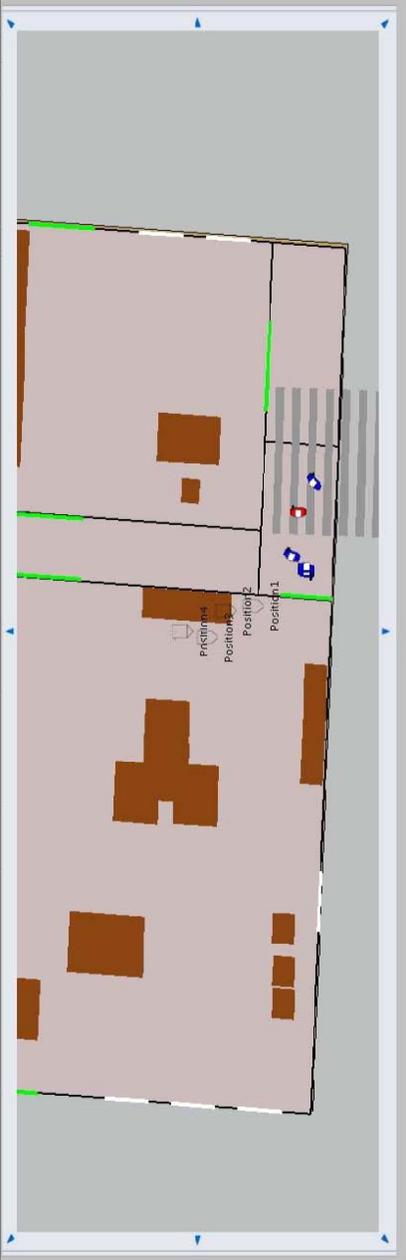

This appendix shows the detailed results of the initial verification of the Clear Room composite behavior. Each section includes the completed tracking spreadsheet from a single scenario within the overall test design.

**This page intentionally left blank.**

Table 50. Clear Room Initial Verification Results, Scenario 1, Page 2.

Room ID	Yes	Given a "small" room to clear, does the team clear or skip the closet?	The entire team enters and clears the closet.	N/A	N/A	Amber (Unable to Verify)	The Use Case does not explain how small enclosures are handled. The Developer mentioned that fire teams are not split in order to clear small rooms. It is not known whether the developer intended to clear a room in this scenario or simply to clear any room to be cleared in this scenario would be considered too small for clearing.
Stack Positions	Yes	Are all four designated stack positions occupied by a team member?	Yes, but in consecutive runs the order of the team members in the stack may not be the same.	N/A	N/A	Amber (Unable to Verify)	Developer indicated that the stack order should be the same in each run of the same scenario.
Enemy Expected	Yes	Does the team member closest to the closet door throw a grenade into the closet?	Yes	N/A	N/A	Green (Passed)	
<b>Rules of Engagement</b>							
General		Use Default ROE	N/A	N/A	N/A	Unverified	
Weapon Control Status		Free	N/A	N/A	N/A	Unverified	
Fire Control Measures		N/A	N/A	N/A	N/A	Unverified	
<b>OTHER</b>							
Stack Position Consistency		N/A	N/A	N/A	N/A	Unverified	
Movement into Room	Check	1. Does the fire team wait for the grenade to detonate before entering? 2. Does the fire team follow the pattern illustrated in the Use Case?	1. Yes. 2. Yes to the extent that the closet's limited space allows.	N/A	N/A	Green (Passed)	
Grenade Status	Check	Since the lead entity in the stack threw a grenade, does the number of grenades in his basic load decrease by 1?	The entity's Status window shows no decrease in the number of grenades.	N/A	N/A	Amber (Unable to Verify)	If shots were fired, or a grenade was thrown, the run was allowed to continue several minutes after the task ended. The Status windows of the entities were then checked to see if the ammunition levels were updated. If an entity's remained unchanged, this was considered an error. This was not an error specific to the behavior.
Enemy Engagement	Check	Do team members engage the enemy as they move towards their set positions in the room?	Out of three runs, no one fired a shot in one run, while shots were exchanged between the team and the enemy in the other two runs. The enemy was fired as the team entered the closet.	N/A	N/A	Amber (Unable to Verify)	
Other 5	N/A	N/A	N/A	N/A	N/A	Unverified	
<b>DATA COLLECTION</b>							
DCST Input Filename	None						
Data Producers							
Data Element							
DC Sub-Category							
Name							
Output Filename	None						
<b>NOTES</b>							
Two of the fire team's members, FIRE-TEAM LEADER1 and RIFLEMAN1, were initially unnamed. Therefore, ammunition was added to their basic loads - each received 200 rounds of 5.56mm Ball, M193, and two Grenade, Hand, M67.							

# Clear Room, Initial Verification, Scenario 3

**Table 53. Clear Room Initial Verification Results, Scenario 3, Page 1.**

<b>General Scenario Description</b>	A five-man fire team is tasked to clear a room occupied by a single entity. The team is initially located inside a building. The room to be cleared is across a hallway from the room the team starts in. Five stack positions (labelled Position 1 through Position 5) are provided in the hallway close to the door of the targeted room. Each stack position is given the same coordinate so they are on top of each other. The fire team expects enemy inside the room.																																															
<b>General Terrain Description</b>	The scenario occurs entirely inside the building.

None																																																

**Table 54. Clear Room Initial Verification Results, Scenario 3, Page 2.**

Optional Parameters		Does the team clear the room?	Yes, but see Discussion.	N/A	N/A	Amber (Unable to Verify)	As the fire team enters the hallway, the first two entities in the formation (TM LDR and RIFLEMAN) enter the hallway through the doorway of the room they are leaving. After RIFLEMAN passes through the doorway, the remaining entities (GRENADEIER, SNIPER and RPG GUNNER) suddenly jump out of the building and enter the hallway by passing through the building's exterior wall. This anomaly occurred in every run. This is amber b/c it appears it is an error with the environmental representation, not the behavior itself.
Room ID	Yes	Does the team clear the room?	Yes, but see Discussion.	N/A	N/A	Amber (Unable to Verify)	As the fire team enters the hallway, the first two entities in the formation (TM LDR and RIFLEMAN) enter the hallway through the doorway of the room they are leaving. After RIFLEMAN passes through the doorway, the remaining entities (GRENADEIER, SNIPER and RPG GUNNER) suddenly jump out of the building and enter the hallway by passing through the building's exterior wall. This anomaly occurred in every run. This is amber b/c it appears it is an error with the environmental representation, not the behavior itself.
Stack Positions	Yes	The five designated stack positions are placed at the same coordinate. Does each team member go to that coordinate when the stack is formed?	Yes	N/A	N/A	Green (Passed)	The Use Case does not mention whether a minimum distance must be maintained between stack positions. If there is no minimum distance, this function passes. Not sure if there is an anti-collision setting that should prevent this convergence at one point.
Enemy Expected	Yes	Does the team member closest to the doorway throw a stun grenade into the room?	No grenades were thrown.	N/A	N/A	Red (Failed)	The Developer mentioned that stun grenades could be thrown, only that their lethality effects are modeled, not their stunning effects. Three runs were completed, but no grenade was thrown in each run.
<b>Rules of Engagement</b>

<b>DATA COLLECTION</b>							
DCST Input Filename	None						
Data Producers							
Data Element							
DC Sub-Category							
Name							
Output Filename	None						
<b>NOTES</b>							
1. This scenario specified the use of stun grenades, but no one in the fire team was armed with these. Therefore two "grenade_Sun_1" were added to each team member's basic load. No one carried fragmentary grenades.							
2. Two of the fire team's members, RIFLEMAN and RPG GUNNER, were initially unarmed. Therefore, in addition to the stun grenades mentioned in Note 1, these two members each received 200 rounds of "5.45x39_Ball_7N6".							
3. This scenario specified a room with a closet located along the path of at least one of the fire team members. This was to test whether the team member would pause by the closet while moving to its set position. Although we found rooms with closets, none of the closets were located along the expected paths of the team members. Therefore this part of the ClearRoom behavior could not be verified.							

**Table 56. Clear Room Initial Verification Results, Scenario 4, Page 2.**

<b>General Scenario Description</b>	A four-man fire team is tasked to clear a room in a multi-story building. The room is located on the first floor on the southeast corner and is occupied by a single opposing entity. The fire team is not provided stack positions and there is no room to assemble the stack to the right side of the door, but there is to the left of the door. The team expects enemy inside the room. There are adjacent rooms all enabled for fire team. The task is to check if the team consistently stacks in the same order. In the first case, the team starts north of the building, enters the building through the north doorway, and approaches the target room from the north. In the second case, the team starts south of the building, enters the building through one of the south doorways, and approaches the target room from the west. In the third case, the team starts on the second floor, moves down the stairwell to the first floor, and when it exits the stairwell, approaches the target room from the west.			
<b>General Terrain Description</b>	The scenario occurs primarily on the ground floor of the building.

<b>OVERALL VERIFICATION RESULTS</b>	<b>Red</b>			
Scenario Verification Status				
Summary	The fire team has a consistent problem engaging the enemy when it enters the room. Of nine runs (three runs for each case), the fire team engaged the enemy just once. In that run, there was a problem positioning the team members in the room. The image at the bottom of this worksheet shows the final positions taken by the team. Two of the positions fall outside the building in addition, it was observed that in consecutive runs, team members did not stack in the same order and that stack order was not maintained when the fire team's initial location was changed.

# Clear Room, Initial Verification, Scenario 5a

Table 57. Clear Room Initial Verification Results, Scenario 5a, Page 1.

<b>General Scenario Description</b>		A four-man fire team is tasked to clear two rooms. The mission is divided into two phases where the team clears the first room during Phase 1 and then clears the second room during Phase 2. Phase 1 is evaluated as Scenario 5a (this scenario) and the Phase 2 is evaluated as Scenario 5b. For Phase 1, no room is specified, stack positions are not provided, and no enemy is expected. The fire team is initially located in a hallway and no opposing entities are present in the building.				
<b>General Terrain Description</b>		The scenario occurs entirely inside the building.

Location of Fire Team wrt Room		Outside					
Room to Stack on Right		N/A					
Stack-Point Locations		Not Too Close Together					
Stack-Location wrt Doorway		Too Far from Doorway					
Stack-Consistency, Excursion		No					
Multi-Room Scenario		Yes					
Room too Small		No					
Closet in Room (along Entry Path)		No					
Grenade Type		Fragmentary					
<b>OVERALL VERIFICATION RESULTS</b>							
Scenario Verification Status		<b>Amber</b>					
Summary The fire team approached the room and each team member occupied one of the designated stack positions. A grenade was thrown down the hallway towards the room despite the stack's distance from the room. The grenade doesn't reach the room and instead creates a breach in the wall. The team entered the room after the grenade detonated. It was observed that in consecutive runs, the team members did not stack in the same order. The round count was not decremented to account for the thrown grenade.							
<b>VERIFICATION PLAN &amp; RESULTS</b>							
<b>TASK/DIALOGUE SETTINGS</b>		<b>Visual Verification Plan</b>	<b>Visual Results</b>	<b>Data Verification Plan</b>	<b>Data Results</b>	<b>Status</b>	<b>Discussion</b>
<b>Header Parameters</b>							
Trigger		On Command				Green (Passed)	Since the first phase cannot be triggered, the fire team never moves from its initial location in the hallway. When the second phase is triggered, the team simply moves down the hallway in file formation towards the designated stack formations. Each member of the team selects a position in the stack. (The same team member may not choose the same stack position in consecutive runs, however.) All members are armed with two fragmentation grenades so the team member closest to the door always throws a grenade down the hallway towards the door. However, because of the distance from the door, the grenade does not reach the room and detonates in the hallway, creating a breach hole in the wall. After the grenade detonates, the team moves into the room. The image at the bottom of this worksheet shows the team at their final positions. The breach hole can also be seen between Position1 and the door. See the inserted graphic below.
WCS Summary		Free					
Enable Reactions for this Task		No	N/A	N/A	N/A	Unverified	
<b>Required Parameters</b>							
None		N/A	N/A	N/A	N/A	Unverified	
<b>Optional Parameters</b>							
Room ID		Yes	Does the team clear the room?	Yes	N/A	Green (Passed)	

**Table 60. Clear Room Initial Verification Results, Scenario 5b, Page 2.**

Stack Positions	Yes	Are all four designated stack positions occupied by a team member?	Yes, but in consecutive runs the order of the team members in the stack may not be the same.	N/A	N/A	Amber (Unable to Verify)	Developer indicated that the stack order should be the same in each run of the same scenario.
Enemy Expected	Yes	Does the team member closest to the doorway throw a grenade into the room?	The team member throws a grenade from his stack position, but because of his distance from the doorway, the grenade doesn't reach the room and it detonates in the hallway, creating a breach hole in the wall.	N/A	N/A	Green (Passed)	It appears that if a grenade needs to be thrown and the lead in the stack has one available, it will be thrown from the lead's location regardless of where the team stacks from the doorway. If this is the intent, then this passes. Since this isn't specified, this criterion is Green.
<b>Rules of Engagement</b>							
General	Use Default ROE	N/A	N/A	N/A	N/A	Unverified	
Weapon Control Status	Free	N/A	N/A	N/A	N/A	Unverified	
Fire Control Measures	N/A	N/A	N/A	N/A	N/A	Unverified	
<b>OTHER</b>							
Stack Position Consistency	N/A	N/A	N/A	N/A	N/A	Unverified	
Movement into Room	Check	1. Does the fire team wait for the grenade to detonate before entering? 2. Does the fire team follow the pattern illustrated in the Use Case?	1. Yes. 2. Yes.	N/A	N/A	Green (Passed)	
Grenade Status	Check	Since the lead entity in the stack threw a grenade, does the number of grenades in his basic load decrease by 1?	The entity's Status window shows no decrease in the number of grenades.	N/A	N/A	Amber (Unable to Verify)	Each run was allowed to continue several minutes after the task ended. The Status window of the lead entity was then checked to see if the grenade count was updated. The amount remained unchanged. This is amber b/c it appears to be an update error, not an error specific to the behavior.
Enemy Engagement	N/A	N/A	N/A	N/A	N/A	Unverified	
Other 5	N/A	N/A	N/A	N/A	N/A	Unverified	
<b>DATA COLLECTION</b>

Data Producers							
Data Element							
DC Sub-Category							
Name							
Output Filename	None						
<b>NOTES</b>							
Two of the fire team's members, FT LDR1 and Rifleman4, were initially unarmed. Therefore, ammunition was added to their basic loads - each received 200 rounds of "5.56mm_Ball_M193" and two "Grenade_Hand_Frag_M67".
