Arthroscopic Preparation of the Posterior and Posteroinferior Glenoid Labrum

Matthew T. Provencher, MD, LCDR, MC, USNR; Anthony A. Romeo, MD; Daniel J. Solomon, MD, CDR, MC, USN; Bernard R. Bach, Jr, MD; Brian J. Cole, MBA, MD

Using an anterior portal for a labral elevator and shaver instrument, with the arthroscope in the anterosuperior portal, allows the posterior and posteroinferior chondrolabral junction to be safely prepared.

A rthroscopic repair of a glenoid labral tear is a common procedure and in certain cases of traumatic shoulder instability, a tear of the posterior or posteroinferior labrum is encountered. Although a number of portals have been described\(^1\)\(^{-4}\) that provide excellent access to place anchors and perform the capsulolabral repair, preparation of the posterior, and posteroinferior glenoid-labral interface may be difficult. Classically, this portion of the labrum has been prepared using a direct posterior or accessory posterolateral portal.\(^4\)\(^{10}\) However, these portals usually provide an unfavorable trajectory that makes insertion of an arthroscopic labral preparation instrument into the chondrolabral junction difficult. This is due to the lack of co-linearity of the cannula relative to the posterior glenoid and labrum.\(^3\)\(^{4}\)\(^{10}\) Because of this trajectory, the labrum may be truncated or inadvertently torn if the posterior and posteroinferior labrum preparation is performed from these portals. This article describes a technique that allows easy access into the chondrolabral junction of this area of the glenoid labrum, without causing damage to the circumferential fibers of the labral tissue.

TECHNIQUE

In a patient with a suspected tear of the posterior labrum, the lateral decubitus is preferred, especially when the pathology is in the posterior or posteroinferior aspect of the joint; an arm traction device provides sufficient traction to easily visualize and work in this area of the joint (Figure 1). Glenohumeral arthroscopy is initiated from a standard posterior portal, which is made slightly lateral than our beach chair posterior portal, such that the lateral edge of the acromion and portal are nearly in-line, and 1 cm inferior to the edge of the acromion. This allows the posterior portal to be angled slightly inferiorly (approximately 15°-20° of inclination) relative to the glenoid rim. An anterosuperior portal is made in the superior aspect of a rotator interval and a clear 5-mm cannula inserted. After the diagnostic glenohumeral arthroscopy is completed, a mid-glenoid (anteroinferior) portal is made just superior to the subscapularis tendon with an 8.25-mm cannula to ensure that the posterior labrum can be accessed. The arthroscope is placed in the anterosuperior cannula over a switching-stick. This then gives excellent visualization to the posterior and inferior aspects of the shoulder joint. The original posterosuperior portal is replaced with a 5-mm cannula over a switching-stick. Alternatively, another
8.25-mm cannula can be placed if a significant posterior plication is warranted. The arthroscope may also be left in the posteroinferior portal if viewing of the posteroinferior quadrant of the glenoid labrum is sufficient.

The posterior labral tear is then identified and probed from the posterosuperior portal (Figure 2). The chondrolabral junction is evident, as the labrum has peeled off the glenoid. An accessory posterolateral portal may be made at this point and an appropriately sized cannula inserted if necessary. The trajectories provided by both of the posterior cannulas make it difficult for a labral elevator device to obtain access to the chondrolabral junction without causing additional damage to the labral tissue (Figure 3).

Instead of using the posterior portals to perform the posterior labral preparation, the mid-glenoid, or anteroinferior portal is used to identify the tear at the chondrolabral junction, and “peel up” and separate the labral tissue from the glenoid surface (Figure 4). In this manner, the mid-glenoid portal allows the arthroscopic labral elevator to traverse directly across the glenoid, enter the chondrolabral junction posteriorly, and elevate the labrum off of the glenoid, much like lifting a pancake off a hot griddle. Once the arthroscopic elevator is sufficiently under the posterior labral tissue, the device can be manipulated in a superior to inferior direction to complete the separation of the chondrolabral junction. A shaver can then be inserted through the mid-glenoid portal to start bony preparation. The bone in this area of the glenoid extends posteriorly from where the labrum normally sits, and can be prepared with the shaver in this manner, taking care not to injure the normal articular cartilage.

After the posterior labrum is sufficiently mobilized, additional preparation may be performed from one of the posterior portals. The posterior and posteroinferior capsulolabral repair can then be accomplished as previously described5,11,12 (Figure 5). Incomplete tears or marginal “cracks” in the posterior labrum have also been described and are also best addressed in a similar fashion with an elevator device from the anterior portal.13

Preventing inadvertent trauma to the labrum or articular cartilage during the labral preparation phase is an important aspect of a capsulolabral repair procedure. The trajectory of the traditional posterior and accessory posterolateral portals make an adequate glenoid labrum preparation difficult to perform. By using an anterior portal for labral elevator and shaver instrumentation, with the arthroscope in the anterosuperior portal, the posterior and posteroinferior chondrolabral junction may be safely prepared.
