Tech Session 1A:
Role of Fire in the Carbon Cycle under Climate Change
Feedbacks between Climate and Fire Emissions

Fires emit significant amounts of trace gases and particulate matter to the atmosphere. These emissions include greenhouse gases, such as CO2 and methane, reactive gases that include a suite of non-methane organic compounds, and various particulate species, including black and organic carbon. Quantifying these emissions and constraining our understanding of their impacts on the atmosphere continues to be an on-going challenge. Recent advances in measurement techniques, remote sensing observations and modeling tools have enabled much better constraints on these processes, yet, large uncertainties remain. There are feedbacks between the fire and climate systems that can control the emissions from fires. Further, once in the atmosphere, fire emissions not only impact atmospheric composition and air quality, but can also influence the climate system in various ways. For example, particulate matter emitted to the atmosphere from fires can have direct radiative effects that can influence local meteorology, as well as processes that control atmospheric chemistry. This talk will address the various emissions from fires to the atmosphere and their controls, including climatic controls. The impacts of fires on the climate system will also be highlighted and the results from recent studies presented.
FEEDBACKS BETWEEN CLIMATE AND FIRE EMISSIONS

Fires emit significant amounts of trace gases and particulate matter to the atmosphere. These emissions include greenhouse gases, such as CO$_2$ and methane, reactive gases that include a suite of non-methane organic compounds, and various particulate species, including black and organic carbon. Quantifying these emissions and constraining our understanding of their impacts on the atmosphere continues to be an on-going challenge. Recent advances in measurement techniques, remote sensing observations and modeling tools have enabled much better constraints on these processes, yet, large uncertainties remain. There are feedbacks between the fire and climate systems that can control the emissions from fires. Further, once in the atmosphere, fire emissions not only impact atmospheric composition and air quality, but can also influence the climate system in various ways. For example, particulate matter emitted to the atmosphere from fires can have direct radiative effects that can influence local meteorology, as well as processes that control atmospheric chemistry. This talk will address the various emissions from fires to the atmosphere and their controls, including climatic controls. The impacts of fires on the climate system will also be highlighted and the results from recent studies presented.
Radiative Forcing of Climate

1. Long-lived GHG emissions
2. Short-lived climate forcers: particles
3. Ozone production
4. Change in surface properties
Fires Impacts on the Climate System

1. Emission of long lived greenhouse gases
   - CO$_2$
     ~ 6-7 Pg CO$_2$ annually released to atmosphere from open burning
   - N$_2$O
   - CH$_4$
2007 Global CO₂ emissions

*Total:* 38 Pg CO₂

*Carbon dioxide emissions are those stemming from the burning of fossil fuels and the manufacture of cement*

*Source:* Carbon Dioxide Information Analysis Center, Environmental Sciences Division, Oak Ridge National Laboratory, Tennessee, U.S.
**CO₂ Emissions from open fires across the U.S.**

*Note:* temporal & spatial variability

Wiedinmyer and Neff, *CBM, 2007*

Black lines represent monthly CO₂ emissions from fossil fuel combustion (U.S. Energy Information Administration)
Fires Impacts on the Climate System

1. Emission of long lived greenhouse gases
   - CO$_2$
     - ~ 6-7 Pg CO$_2$ annually released to atmosphere from open burning
   - N$_2$O
   - CH$_4$

2. Direct emission of short-lived climate forcers
   - Black Carbon
   - Particulate organic matter

3. Production of tropospheric ozone and secondary organic particulate matter

(e.g., Andreae et al., 2004; Rosenfeld 1999)
Use coupled weather-chemistry model to investigate the feedbacks between the fire emissions, weather, and chemistry.

Jiang, Wiedinmyer and Carlton, *in preparation*
Regional feedbacks to weather and chemistry

- Inclusion of fire particulate emissions:
  - Reduction in shortwave radiation
  - Reduction in surface temperature
  - Change in PBL height
  - Decreases in atmospheric water vapor mixing ratio
  - Change ozone concentrations

Fire emissions have regional climate impacts:
- Meteorology and chemistry
- Local and regional effects
- Short-lived impacts

Jiang, Wiedinmyer, and Carlton, in preparation
Fires Impacts on the Climate System

1. Emission of long lived greenhouse gases
   - $\text{CO}_2$
   - $\sim 6-7 \text{ Pg CO}_2$ annually released to atmosphere from open burning
   - $\text{N}_2\text{O}$
   - $\text{CH}_4$

2. Emission of short-lived climate forcers
   - Black Carbon
   - Particulate organic matter

3. Production of tropospheric ozone and secondary organic particulate matter

4. Changes in land surface properties
   - Black carbon on snow
   - Albedo
Radiative Forcing of Black Carbon on Snow

Bond et al., ACP, 2011
Fire impacts on climate: Land Cover Change

Post Fire Impacts:
- Surface temperature
- Vegetation production
- Albedo

Impact of fire disturbance on land surface energy and carbon balances. In the summer of 2002, the Biscuit Fire in Oregon destroyed 2000 km² of temperate evergreen forests (left). A Moderate Resolution Imaging Spectroradiometer (MODIS) satellite image taken on 28 July 2003 (middle) shows land surface radiometric temperatures of 46° to 50°C in the area burned the summer before, whereas temperatures in the adjacent unburned forests range from 27° to 32°C. Annual vegetation production measured from MODIS (4) (right) was 20 to 60% lower in the burned area in 2003 to 2004 than before the wildfire.

Concluding Remarks

- Emissions from open biomass burning are substantial – at global and regional scales

- Fires can have many impacts on the regional and global climate system
  - Highly non-linear
  - Impacts occur on various time scales

- Our range in understanding of the emissions and their feedbacks remains large

Increased cloud lifetime effect/2nd indirect effect/Albrecht effect

Cloud albedo effect/1st indirect effect/Twomey effect

Surface

Heating causes cloud burn-off (Ackerman et al., 2000)

Semi-direct effect

Figure 2.10. Schematic diagram showing the various radiative mechanisms associated with cloud effects that have been identified as significant in relation to aerosols (modified from Haywood and Boucher, 2000). The small black dots represent aerosol particles; the larger open circles cloud droplets. Straight lines represent the incident and reflected solar radiation, and wavy lines represent terrestrial radiation. The filled white circles indicate cloud droplet number concentration (CDNC). The unperturbed cloud contains larger cloud drops as only natural aerosols are available as cloud condensation nuclei, while the perturbed cloud contains a greater number of smaller cloud drops as both natural and anthropogenic aerosols are available as cloud condensation nuclei (CCN). The vertical grey dashes represent rainfall, and LWC refers to the liquid water content.
