(Received 23 November 2010; accepted 20 December 2010; published online 6 January 2011)

Strain state of ultrathin InAs-on-insulator layers obtained from an epitaxial transfer process is studied. The as-grown InAs epilayer (10–20 nm thick) on the GaSb/AlGaSb source wafer has the expected ~0.62% tensile strain. The strain is found to fully release during the epitaxial transfer of the InAs layer onto a Si/SiO2 substrate. In order to engineer the strain of the transferred InAs layers, a ZrO2 cap was used during the transfer process to effectively preserve the strain. The work presents an important advance toward the control of materials properties of III-V on insulator layers. © 2011 American Institute of Physics. [doi:10.1063/1.3537963]

III-V compound semiconductors have been extensively explored in the recent years for energy-efficient and high-speed electronics due to their high electron mobility and saturation drift velocity.1–3 In this aspect, ultrathin, fully depleted layers are desired to reduce device leakage (i.e., off-state) currents, especially since many high mobility III-V semiconductors exhibit small bandgaps. Recently, the epitaxial transfer1–5 of ultrathin (thickness, hInAs=8–48 nm) InAs layers on Si/SiO2 substrates was demonstrated by our group with the subsequently fabricated field-effect transistors exhibiting excellent electrical properties.3 This compound semiconductor on insulator (termed XOI) technology presents a viable route toward the heterogeneous integration of III-V semiconductors on Si substrates without the use of complex heteroepitaxial growth processes. Of particular importance is to explore the strain state of the ultrathin XOI layers, and more crucially, to control it since strain plays a critical role in the electronic properties of materials.5 Specifically, strain directly tailors the band offsets and carrier mobility by lifting the degeneracy in the bands which have been thoroughly investigated for heteroepitaxially grown multilayers.6–9 In this paper, we investigate the strain state of ultrathin InAs XOI layers and demonstrate strain engineering by the use of a ZrO2 capping layer during the epitaxial transfer process.

The fabrication process for the InAs XOI substrates is shown schematically in Fig. 1(a) as previously reported in Ref. 3. Briefly, InAs thin films (hInAs=10–20 nm) were grown epitaxially on a 60 nm thick AlxGa1−xSb (x=0.2–1) sacrificial layer on GaSb (001) substrates. The ultrathin InAs layers were lithographically patterned (width of 350 nm–5 μm) and wet etched using a mixture of citric acid [1 g/ml in de-ionized (DI) H2O] and hydrogen peroxide (30%) at 1:20 volume ratio. Subsequently, the AlGaSb sacrificial layer was selectively etched in ammonium hydroxide (1.5%, in DI H2O) solution. The partially released InAs micro- or nanoribbons [Fig. 1(b)] were transferred onto Si/SiO2 receiver substrates using an elastomeric polydimethylsiloxane substrate (~2 mm thick). In order to engineer the strain of

Approved for public release; distribution unlimited
transferred InAs layers, a ZrO$_x$ (or SiO$_x$) capping layer was deposited by electron-beam evaporation on top of the source wafer prior to the epitaxial transfer process [Fig. 1(a)]. ZrO$_x$ was chosen as the cap material because (1) ZrO$_x$ is known to have a good interface with InAs (Ref. 3) which is beneficial for the eventual device fabrication and (2) ZrO$_x$ has a large Young’s modulus (130–250 GPa). The cap prevents the relaxation of strain in InAs during the XOI fabrication process as shown later in detail in this paper. Figures 1(c) and 1(d) show the transmission electron microscopy (TEM) images of an InAs XOI substrate, clearly depicting the single-crystalline structure of the InAs layer on an amorphous SiO$_2$ layer. No clear voids are evident at the InAs interfaces, although it should be warned that TEM analyzes only a small cross-sectional area.

The structure of the source wafer is shown schematically in Fig. 2(a), with both InAs and AlGaSb layers coherently strained to the GaSb (001) substrate as confirmed by high resolution x-ray diffraction (HRXRD). Specifically, we used Ω-2θ coupled scan, where Ω is the incident angle between the x-ray source and the sample and 2θ is the diffraction angle between the incident beam and diffraction beam, to resolve the (004) peaks from InAs, AlGaSb, and GaSb and extract the out-of-plane lattice parameters, $a$. Figure 2(b) shows the diffraction spectra taken from GaSb/Al$_{0.2}$Ga$_{0.8}$Sb/InAs source wafers with $h_{\text{InAs}}=10$, 15, and 20 nm, referenced to the peak of GaSb substrate, which has a (004) Bragg angle at 30.3 ± 0.1°. Using Bragg’s law $2d \sin \theta = \lambda$, where $d$ is the distance between the (004) crystal plane ($d=a/\sqrt{2}$), $n=1$, and $\lambda$ is the x-ray wavelength (Cu’s Ka), one obtains $a \sim 6.02$ and 6.11 Å for InAs and Al$_{0.2}$Ga$_{0.8}$Sb, respectively (note that $a_{\text{GaSb}} \sim 6.10$ Å, which is the bulk GaSb lattice parameter). From the equation $a_{\text{InAs}}=a_{\text{GaSb}}+\Delta a$, where $a_{\text{InAs}}$ and $a_{\text{GaSb}}$ are the elastic compliance constants and $a_0$ is the bulk lattice parameter, the in-plane lattice parameter $a_0$ for both InAs and Al$_{0.2}$Ga$_{0.8}$Sb is found to be $\sim 6.10$ Å, which is the same as that of GaSb (001). The experimental spectra also precisely match the simulation data [Fig. 2(b)], which assume that both Al$_{0.2}$Ga$_{0.8}$Sb and InAs layers are biaxially strained such that their $a_{\text{InAs}}$’s are the same as that of the GaSb substrate. The result is consistent with the fact that the thicknesses of the AlGaSb sacrificial layer and the InAs layer are within their theoretical critical thicknesses for heteroepitaxy of $h_{\text{cr}}\sim 10.2$ μm and 240 nm for Al$_{0.2}$Ga$_{0.8}$Sb and InAs, respectively, which can be calculated from the empirical equation $h_{\text{cr}}=\left[\frac{\Delta a}{\Delta a_{0,\text{GaSb}}}\right]^2$, where $\Delta a=16$ and $n=2.4$ for III–V’s. 

To visualize the strain state of the InAs layer in the XOI system (i.e., after transfer on Si/SiO$_2$ substrate), micro-Raman spectroscopy was employed. Note that Raman spectroscopy could not be used for the analysis of the source wafer since InAs, AlGaSb, and GaSb have overlapping phonon peaks. Figure 3(a) shows the Raman spectra of InAs XOI ($h_{\text{InAs}}=20$ nm) obtained from source wafers with different composition of Al$_{x}$Ga$_{1-x}$Sb sacrificial layers ($x=0.2, 0.4,$ and 0.6) along with the [001] bulk InAs data from literature. Here, no capping layer was used during the epitaxial transfer process. The spectra distinctly depict the first order transverse optic mode (−217 cm$^{-1}$), longitudinal optic (LO) mode (−239 cm$^{-1}$), and the low frequency branch of coupled LO-phonon-plasmon mode (L-) (−230–235 cm$^{-1}$) phonon peaks of InAs XOI. Clearly, InAs XOI layers obtained from sacrificial layers with different compositions exhibit near identical Raman spectra, with the LO peak position at $\sim 239$ cm$^{-1}$ which is the same as that for the InAs bulk substrate [Fig. 3(a)]. Furthermore, the position of the LO peak is identical for InAs with thicknesses $h_{\text{InAs}}=10–20$ nm [Fig. 3(b)]. The results suggest that in the absence of a ZrO$_x$ capping layer, the strain is fully released during the epitaxial transfer process. We hypothesize that the strain is released upon the partial etch of the AlGaSb layer, which results in nearly free-standing InAs layers [Fig. 1(b)]. The L-peak, which is due to the surface plasmon-LO phonon
coupling, however, exhibits a $h_{\text{InAs}}$ dependence [Fig. 3(b)]. One possible reason for the increasing L/LO intensity ratio with reducing InAs thickness is due to the enhancement of the surface area to volume ratio. For all measurements, the intensity of the Raman laser power was decreased until the peak positions did not show any dependence on the laser intensity. This ensured a more accurate estimation of the phonon peak locations, without laser-induced heating.

A redshift of $2.9\pm1.1$ cm$^{-1}$ in the LO peak position is clearly evident for InAs XOI layers transferred with a 70 nm ZrO$_2$ cap as compared to those without a cap [Fig. 3(c)]. The amount of tensile strain inside the InAs XOI layer transferred with a cap was extracted from $\Delta \omega/\omega = (K_{11}/2)e_{xx} + (K_{12}/2)(e_{yy} + e_{zz})$, where $\omega$ is the LO peak location (238.6 cm$^{-1}$), $\Delta \omega$ is the LO peak shift, $K_{11} = -1.753 \times 10^{11}$ dyn/cm$^2$, and $K_{12} = -2.323 \times 10^{11}$ dyn/cm$^2$ are the anharmonic spring constants for InAs LO phonon, and $e_{xx} = e_{yy} = -2C_{12}/C_{11}$, $e_{zz} = -2C_{12}/C_{11}$ are components of strain tensor inside InAs, with $C_{11} = 8.329 \times 10^{11}$ dyn/cm$^2$ and $C_{12} = 5.452 \times 10^{11}$ dyn/cm$^2$ as the elastic compliance constants of InAs.\textsuperscript{10,16} From this analysis, we obtain an in-plane strain $e_{xx} = e_{yy} = 0.8 \pm 0.3\%$, which is within the expected range of the $\sim 0.62\%$ initial strain of the as-grown InAs layer. We note that besides preserving the initial strain of the transferred InAs layer, the ZrO$_2$ cap may also induce additional strain depending on its initial stress level upon evaporation.

To relate the amount of strain remaining in the InAs XOI layer to the ZrO$_2$ cap thickness, analytical modeling was performed as shown in Fig. 4. For simplicity, it was assumed that the InAs and ZrO$_2$ layers deform equally after release from the sacrificial layer and that the relationship between strain and stress is linear, given by Young’s modulus $E$. Figure 4(a) schematically illustrates the stress distribution across a cross-section of the ZrO$_2$ cap and InAs layer. The stress in each layer can be found by setting a common absolute deformation value, and the relationship between these two stresses can be set by zeroing the net moment caused by them. The remaining stress inside InAs is then determined by the following equation: $\varepsilon = mn(n+2)e_0/[1+mn(n+2)]$, where $E_{\text{ZrO}_2}/E_{\text{InAs}} \sim 2.63$ is the ratio of Young’s moduli of ZrO$_2$ and InAs, $n = h_{\text{ZrO}_2}/h_{\text{InAs}}$ is the ratio of the thicknesses of ZrO$_2$ and InAs, $e_0 = 0.62\%$ is the as-grown InAs strain. The dependence of the strain ($\varepsilon$) in a 20 nm InAs layer on the cap thickness ($h_{\text{ZrO}_2}$) is plotted in Fig. 4(b). The modeling indicates that the initial InAs strain is nearly fully maintained (by up to $\sim 98\%$) by a 70 nm ZrO$_2$ cap, which is consistent with the experimental observations.

In conclusion, the strain state of InAs layers within the XOI platform was studied. The results highlight that the strain of the X layer in XOI can be tuned by choosing different cap layers (with different Young’s moduli), cap thicknesses, and the initial stress inside the cap to obtain the optimal strain level for the desired device application. The presented approach adds yet another degree of versatility to the use of epitaxial layer transfer technique of ultrathin semiconductors for device applications.
