1. Introduction

There are two search tasks in TREC2012 Microblog Track\textsuperscript{[1]}, namely: Real-time Adhoc and Real-time Filtering. The Tweets2011 corpus is used again and last year’s results can be used as first officially labeled data for any participants to train their models. In this year’s track, the former task has 60 new queries given and the latter is first proposed.

In the Real-time Adhoc task, we use indri retrieval toolkit\textsuperscript{[2]} to construct our retrieval system and propose a strategy of pseudo relevance feedback to expand original query, then we retrieved original tweets and their indri’s scores as an important feature. Besides, we calculate lots of other features of these tweets, such about url, hash_tag, entropy, tfidf, bm25, language model\textsuperscript{[3]} and proximity\textsuperscript{[4]}. At last, we use two learning-to-rank methods, specifically RankSVM\textsuperscript{[5]} and ListNet\textsuperscript{[6]}, to combine all those features to sort them, returning the final ranked tweets to a specified query.

In the Real-time Filtering task, we assume this task is similar with the topic tracking in Twitter Stream\textsuperscript{[7]}. We build up two filtering models based on language model and Vector Space Model respectively. Each model is initialized by the start query and its relevant tweets. For each new coming tweet, the model will decide whether it is under the topic. If it is, we update the model to keep up with the development of the topic.

The rest of this paper is organized as follows. In Section 2, we discuss the preprocessing of Tweets2011 corpus. In Section 3, the main method to rank the search results in Real-time Adhoc task is discussed. In Real-time Filtering task, we describe two filtering models in Section 4. Experiment results are reported in Section 5. And in the last section, we draw conclusions about our work.

2. Data preprocessing

We use our last year’s preprocessed corpus\textsuperscript{[8]}. As tweets can be deleted or protected after posting, we additionally use an updating tweet ids list to remove tweets deleted from the corpus recently. Besides, word stemming is reprocessed and stop word removing is not processed as this will cause a large portion of information in such short text lost. Finally, there are 7,443,387 tweets in our data set.

3. Real-time Adhoc

3.1 Query expansion

We leverage both internal and external expansions. In internal expansion, we assume the retrieved top tweets which have the most ranking scores are more relevant to the topic. When viewing the top tweets as a document, we can estimate each word’s new weight according to,

Standard Form 298 (Rev. 8-98)
Prescribed by ANSI Std Z39-18
Weight(T) = \frac{idf(T)}{\text{Sum\_Score}(D(K))} \sum_{d \in D(K)} \text{score}(d) \cdot tf(d, T)

where D(K) indicates the top-K returned tweets from the original query, Sum\_Score(D(K)) is the sum of top-K tweets’ scores, \( tf(d, T) \) is the term frequency of \( T \) in tweet \( d \) and \( idf(T) \) is the global inverse document frequency of term \( T \) in the corpus.

Besides, we use term concurrency frequency in the corpora as a second method to choose expansion words, their weights are estimated in following formula, where \( tc(T) \) indicates the frequency of term \( T \) concurrency with query terms, and it is normalized by \( \sum_{t \in d} tc(t) \).

\[
\text{Weight}(T) = \frac{1}{\text{Sum\_Score}(D(K))} \sum_{d \in D(K)} \text{score}(d) \cdot \frac{tc(T)}{\sum_{t \in d} tc(t)}
\]

In external expansion, we use Google Search Engine to fetch result page of the original query. All words occurred in top three links’ titles are chosen to be the expansion words.

At last, we use Indri Retrieval Language to combine these expansion words and original query considering their new weights\(^9\).

### 3.2 Features

We used two types of features, including static features (query independent) and dynamic features (query dependent, in both original and expanded queries, proximity features are only in original queries). For every result tweet, there are totally 51 features to be estimated (listing in the following tables). As the pages are limited, we can’t describe every feature in details. Fortunately, lots of features can be described by their names, so we only choose some nameless features to describe.

<table>
<thead>
<tr>
<th>Static Features</th>
<th>Dynamic Features</th>
</tr>
</thead>
<tbody>
<tr>
<td>has_url, has_hashtag, has_rt;</td>
<td>covered_term_ratio;</td>
</tr>
<tr>
<td>url_slash_count_min,</td>
<td>tf_sum, tf_min, tf_max, tf_mean, tf_variance;</td>
</tr>
<tr>
<td>url_slash_count_max,</td>
<td>tfidf_sum, tfidf_min, tfidf_max;</td>
</tr>
<tr>
<td>url_slash_count_mean,</td>
<td>tfidf_mean, tfidf_variance;</td>
</tr>
<tr>
<td>url_len_min, url_len_max, url_len_mean;</td>
<td>boolean_model, vsm, bm25;</td>
</tr>
<tr>
<td>oov_ratio, unique_word_ratio, doc_len;</td>
<td>lmir_dir, lmir_jm, lmir_abs;</td>
</tr>
<tr>
<td>begin_with_at, indri_score, entropy;</td>
<td>min_proximity;</td>
</tr>
<tr>
<td></td>
<td>mean_proximity;</td>
</tr>
</tbody>
</table>

In static features, indri_score is returned from our Indri Retrieval System, oov_ratio is the ratio of out-of-vocabulary words count over the total words count, unique_word_ratio is similar to oov_ratio.

In dynamic features, \( tf \) value is query term frequency in a tweet,\( tf\)-idf value is the query termtf-idf weight in a tweet. boolean_model, vsm, bm25, lmir (language model for IR) are the scores of the query to a tweet under these retrieval models. In lmir, three smoothing methods are used respectively, including DirichletPrior(dir), Jelinek-Mercer(jm) and Absolute Discounting(abs). We also estimate query proximity in a tweet.
3.3 Learning to Rank Methods

We utilize a simple linear learning-to-rank model to combine all these aforementioned features. Given a query Q and a tweet D, a relevance score \( s(Q,D) \) is computed according to:

\[
s(Q,D) = \sum_{i=1}^{N} \lambda_i f_i(Q,D)
\]

where \( N \) is the total number of features, \( f_i(Q,D) \) is a feature value and \( \lambda_i \) is a model parameter. Given a query Q, tweets D are ranked in descending order of their relevance score. To estimate model parameters, we use two types of learning-to-rank approaches, specifically RankSVM\(^5\) for Pairwise approach and ListNet\(^6\) for Listwise approach. Last year’s queries and results are used for training, and 5-fold cross-validation is utilized.

4. Real-time Filtering

We assume this task is similar with the topic tracking in Twitter Stream\(^7\), however, there are some differences in our approach.

A quality score is defined as a static weight for each tweet. The quality score is used to measure the probability of whether a tweet’s content is meaningful, and is treated as a global weight for each tweet. We adopted the logistic regression model to calculate the quality scores. The features consist of several static features extracted in Adhoc task. And the tweets of the given 10 training topics are used as learning samples.

Two different retrieval models are utilized to implement two filters respectively. In the filter based on language model, we choose stupid backoff as the smoothing technique and “queue” as the history retention technique\(^7\). In the filter based on vector space model, \( \text{tf} \) value is calculated in the “foreground” model and \( \text{idf} \) comes from the “background” model\(^7\), and we also use the “queue” strategy to retain history information.

5. Experiments and Results

In Real-time Adhoc task, 60 queries are tested and four runs are submitted with different query expansions and different learning-to-rank methods. \( \text{tf/idf} \) query expansion is used in ICTWDSERUN1, and concurrency frequency query expansion is used in ICTWDSERUN2. In both ICTWDSERUN3 and ICTWDSERUN4, we use google search results as query expansion. RankSVM method is used in both ICTWDSERUN1 and ICTWDSERUN3, while LiseNet method is used in both ICTWDSERUN2 and ICTWDSERUN4. For each topic we return 10000 tweets in ICTWDSERUN1, and 1000 in both ICTWDSERUN2 and ICTWDSERUN3, but in ICTWDSERUN4 the returned tweets’ number is estimated by a k-means method. The following table shows our results.

<table>
<thead>
<tr>

Table I. Experiments Results in Real-time Adhoc Task
In Real-time Filtering task, 40 topics are tested and four runs are submitted with different retrieval models and initialized strategies. VSM is used in both ICTNETFTRUN1 and ICTNETFTRUN2, and Language Model is used in both ICTNETFTRUN3 and ICTNETFTRUN4. To initialize the original topic we only use data in the corpus in ICTNETFTRUN1 and ICTNETFTRUN3, while we use the top-3 Google search results as an external resource in ICTNETFTRUN2 and ICTNETFTRUN4. The following table shows our results.

<table>
<thead>
<tr>

</tbody>
</table>

6. Conclusion

In Real-time Adhoc task, we propose 51 features and use them in two learning-to-rank models which are trained by last year’s results of the task. Finally, four runs are submitted with different query expansions. In Real-time Filtering task, we construct two filtering models to track topic in the stream of tweets, two runs are submitted with different tracking models.
