Abstract

The most cost-effective and feasible strategy for managing any recently established non-native invasive plant species (NIS) is early detection and rapid response. However, conventional sampling designs can be inefficient and costly to implement when sampling early phases of invasion. Adaptive sampling designs were specifically developed as alternatives to conventional sampling to take advantage of the rarity and clustered nature of many biological populations. One class of adaptive sample designs is adaptive web sampling, which provides a balance between increasing sampling in the immediate proximity of an already detected patch and sampling farther away from the detected patch to locate more distant satellite patches. This balance makes adaptive web sampling well suited for mapping NIS in early invasion phases when invasive populations are rare and locally clustered. Adaptive web sampling is also more flexible than other adaptive designs because the amount of sampling effort allocated to adaptive selection can be based on local factors.

This manual describes an adaptive web sampling design and a user-friendly GPS interface developed to aid implementation of the sampling design in the field. The GPS user interface is a customized application developed for ESRI’s (Redlands, CA) ArcPad® mobile geographical information system (GIS) software.

Preface

This study was conducted for the Department of the Army, Office of the Director of Environmental Programs under Program Element A896, “Base Facility Environmental Quality”; Project 030F25, “Dynamic Adaptive Inventory and Mapping of Non-Native Invasive Plants on Army Installations.” The technical monitor was Steve Sekscienski.

The work was completed as part of a cooperative agreement between Montana State University and the US Army Engineer Research and Development Center – Construction Engineering Research Laboratory (ERDC-CERL). The ERDC-CERL work was performed by the Ecosystem Processes Branch (CN-N) of the Installations Division (CN). At that time, William Meyer was Branch Chief, CN-N; Dr. John Bandy was Chief, CN; and Alan Anderson was Technical Director for Environmental Quality. The Deputy Director of ERDC-CERL was Dr. Kirankumar Topudurti and the Director was Dr. Ilker Adiguzel.

COL Kevin J. Wilson was the Commander and Executive Director of ERDC, and Dr. Jeffery P. Holland was the Director.
1 Introduction

1.1 Background

It has been estimated that approximately 275,000 acres\(^1\) of Army training and testing land currently have restrictions on use related to non-native invasive plant species (NIS), which are introduced to areas by a variety of natural and anthropogenic means. Once established, some NIS can threaten the ecological integrity of native plant communities and alter important ecosystem-level properties, such as hydrology, disturbance regimes, nutrient cycling, and microbial processes (Vitousek et al. 1989; Mack et al. 1998; D’Antonio 2000; Zavaleta 2000; Brooks et al. 2004; Ehrenfeld 2004; Bais et al. 2006; Allan et al. 2010, Hickman et al. 2010). This potential threat has made the management of NIS on federal lands, including Army training lands, mandatory by Executive Order 13112, “Invasive Species.”\(^2\)

NIS populations can be extremely difficult and expensive to eradicate once established. A more economical and ecologically viable means of limiting NIS impacts is to prevent harmful, unwanted NIS from arriving in an area in the first place (Moody and Mack 1988; Davies and Sheley 2007). Unfortunately, NIS management strategies based on prevention have limited feasibility on Army training lands. Army land use is unique among federal land stewards. Military operations such as off-road maneuvers, moving equipment, material, and personnel between sites, and driving considerable distances along unpaved roads, pose a high risk of transporting NIS propagules within and between sites. The high degree of vegetation and soil disturbance associated with training maneuvers also facilitates the establishment of NIS that are dependent upon or benefited by disturbance. Limiting access to areas infested by NIS as a means of preventing unintended transport of NIS propagules is also unviable, given that training land availability does not meet established needs. Military bases do have vehicle wash stations to clean vehicles travelling within and between sites. Although this approach can reduce the number of plant propagules on a vehicle, it does not totally remove the risk. Thus, some new NIS populations are likely to establish as a result of vehicle movements. The most cost

\(^1\) 1 acre = 4,046.873 square meters

\(^2\) Issued by President Clinton on February 3, 1999, and published 64 FR 6183, February 8, 1999.
effective and feasible strategy to address any new and recently established NIS populations is “early detection and rapid response (EDRR),” i.e., treatment, while they are still infrequent on the landscape (Davies and Sheley 2007). There is frequently a lag time between introduction of NIS and the occurrence of rampant population growth and corresponding impacts (Hobbs and Humphries 1995). Treatment of small NIS populations during this lag phase can prevent widespread invasion and establishment. However, early treatment is dependent upon accurate detection and mapping (Dewey and Anderson 2004; Barnett et al. 2007).

Paradoxically, it is during the lag phase between introduction and rapid population growth that NIS can be the most challenging to detect and map. The large spatial extent of some managed areas coupled with limited financial resources and competing priorities can make it impossible to conduct the complete inventory and mapping effort needed to document NIS distributions. These restraints necessitate sampling of some type to be performed. Conventional sampling designs can be inefficient and costly to implement, however, when used to sample sparsely and/or small, patchily distributed populations that typify early phases of invasion. To increase the number of patches detected using conventional sampling methods, sample size must be increased, but many sampling units will not contain species of interest (Morrison et al. 2008).

Adaptive sampling designs are an alternative to conventional sampling specifically developed to concentrate sampling effort in “hot spots” or areas with a high probability of finding the target species of interest. By concentrating sampling effort where target species are most likely to be found (i.e., near other target species), the problem of visiting unoccupied sampling units is minimized. Adaptive sampling methods can, therefore, be more efficient at detecting sparsely dispersed NIS populations, when efficiency is evaluated in terms of the amount of time spent sampling and travelling between sampling unit locations.

One class of adaptive sample designs is adaptive web. This class of designs focuses on sampling populations in networks or ones that exhibit spatial structure. Like all adaptive sampling designs, designs in this class adjust sampling intensity during the sampling process to allocate more effort in areas that are most promising. Designs in the class, however, are more flexible than other adaptive designs, because the amount of sampling effort allocated to adaptive selection is not constant and can be based on
local factors. Any remaining effort can be allocated to sampling units selected at random from within the population or sampling frame. Consider, for example, a simple adaptive cluster design implemented using a grid. The grid is composed of square cells of fixed dimension and, once a target species is located in a cell, the two neighboring cells directly to the right and left and above and below the cell containing the target species are adaptively sampled. Adaptive sampling continues in this manner — adding all four neighboring cells — until no more target species are located. Now consider an adaptive web sampling design with a basic adaptive sampling unit selection algorithm proposed by Thompson (2006) implemented over the same grid. The selection algorithm is as follows: when a target species is located in a cell, with probability $p = 0.9$ a neighboring cell is sampled, while with a probability $1 - p = 0.01$, a cell is selected at random from within the grid to sample. Sampling continues in this way until no more target species are located within any of the cells chosen to sample. Only 90% of the neighboring cells are sampled with this adaptive web, as opposed to 100% with the adaptive cluster design. Thus, when sampling for NIS, adaptive web designs can provide a balance between increasing sampling in the immediate proximity of an already detected patch and sampling farther away from the detected patch looking for more distant satellite patches. It is this balance between sampling near and far from an existing patch that makes the designs well suited for surveying NIS in the early phases of invasion when the populations are rare and clustered within a management area.

1.2 Objectives

This manual describes an adaptive web sampling design (AWS) and a user friendly Global Positioning System (GPS) interface developed to aid implementation of the sampling design in the field. The GPS user interface is a customized application developed for ESRI® (Redlands, CA) ArcPad®, a mobile geographical information system (GIS) software for field applications. ArcPad is designed to integrate with ESRI’s desktop GIS technology, ArcGIS®. Using the ArcPad application is not possible without this software.

The objective of the sampling design and ArcPad application described in this manual is to assist Army land managers who want to use an EDRR NIS management strategy to detect and map the locations of NIS populations, a crucial first step in the strategy. In addition, because ArcPad is fully integrated with ArcGIS and requires a geodatabase, the geodatabase
can become part of a longer term NIS monitoring program to assist Army
land managers in planning, budgeting, prioritizing, and later tracking the
effectiveness of NIS management actions.

1.3 Method of technology transfer

The information in this report will be made accessible to users through the
Engineer Research and Development Center’s (ERDC’s) online document
repository: http://acwc.sdp.sirsi.net/client/default.

The software will be made available via download from the Montana State
University, Weed and Invasive Plant Ecology and Management Group’s
website:
http://weedeco.msu.montana.edu/rangewildland/Herbaceous_invading_plant_species.html.
2 Adaptive Web Sampling Background

2.1 Adaptive web sampling design

A sampling design specifies the rules for which sampling units of the population are included in the sample during a survey. In conventional sampling designs, all the sampling units in the sample can be specified prior to conducting a survey. In adaptive sampling designs, some sampling units in the sample are specified prior to conducting a survey, while others are added to the sample during the survey. Sampling units are selected and added to the sample during the survey when some inclusion criterion is met. For the AWS, the inclusion criterion is the presence of one or more plants of the target NIS.

The AWS is a two-stage sequential design, similar to Thompson (1991) and Salehi and Smith (2005), where a set of secondary sampling units are selected once a target NIS is found within the primary sampling unit. The secondary sampling unit is a square polygon of fixed area referred to as a cell. The primary sampling unit, referred to as a transect, consists of a group of X-number of contiguous cells, where X is an integer greater than zero. The AWS implements the simple adaptive web strategy suggested by Thompson (2006) over a spatial network. In this strategy, the nodes of the networks are cells and the links between nodes are defined by adjacency, i.e., each cell is linked to its adjacent neighbors (at most eight). When a NIS is detected in a cell, some but not all the cell’s neighboring cells are added to the sample (i.e., the link between the cells is chosen or followed). Whether or not a neighboring cell gets added to the sample is determined probabilistically with probability p. When, with probability $1 - p$, a neighboring cell is not chosen to be added to the sample, another cell within a predefined area is randomly chosen in its place. A predefined area from which random cells can be selected is associated with each transect and is called the survey grid. The survey grid consists of the group of cells formed by adding an equal number of cells to the right and left of each transect cell. For example, if a transect consists of 10 cells and 3 cells are added to the right and left of each transect cell, then the survey grid would be a group of 70 cells.

In the AWS, the probability, $p$, that a link between adjacent cells is chosen once a plant is detected reflects the biology of the NIS and is a function of
both the type of spatial pattern exhibited by the plants in the cell and the
variability of the local environment surrounding the cell. More specifically,
let cell_i be any secondary sampling unit, p_i be the probability a link from
cell_i to one of its neighboring cells is followed once a plant is detected in
cell_i, then the value of p_i associated with cell_i is as follows;

\[ p_i = P_{sp}, \text{ if pattern}_i = \text{individual scattered plants}; \]
\[ p_i = LHV_i / 9, \text{ if pattern}_i = \text{discrete patches, or interconnected patches}, \]

where:

\[ P_{sp} = \text{a constant that is fixed per survey and is set prior to} \]
\[ \text{conducting a survey} \]
\[ \text{pattern}_i = \text{the spatial distribution pattern of the plants in cell}_i \]
\[ LHV_i = \text{local variability of the environment surrounding cell}_i \]

(described below).

The local variability of the environment surrounding cell is a measure of
local environmental heterogeneity. It needs to be calculated for each cell in
the survey area prior to conducting a survey using the spatial analyst focal
function in ArcGIS and a GIS data layer of some environmental variable
such as terrain aspect or land cover type. The focal function calculates, for
each cell in the layer, the number of different values of the environmental
variable found in a nine cell neighborhood centered at the cell. If the
environmental variable is terrain aspect, for example, then the focal func-
tion would calculate the number of different aspect values in the nine cell
neighborhood surrounding a cell (see Figure 2-1). Other possible environ-
mental variables include slope, elevation, aspect, soil type, annual radia-
tion, and distance to rights-of-way.

The AWS is analogous to an adaptive cluster sampling design with all eight
neighboring cells being adaptively sampled upon location of an NIS in a
cell, if environmental homogeneity is assumed and \( P_{sp} = 1 \). Assuming
environmental homogeneity is equivalent, in this situation, to assuming
\( LHV_i = 9 \) for all cells. With \( LHV_i = 9 \) for all cells and \( P_{sp} = 1 \), the probability
of following a link between cells is always one and thus, all links are fol-
lowed once an NIS is found.
2.2 Adaptive web sampling ArcPad application

The AWS ArcPad application, referred to from this point forward simply as the Applet, is a user-friendly ArcPad GPS interface written in Visual Basic Scripting language. It was developed and tested for ArcPad 8.0 on a Trimble GeoXT GPS device, but should run on any mobile device that supports ArcPad. The Applet requires certain GIS feature classes in a geodatabase; hence, it requires ESRI ArcGIS. It functions as a navigational GPS data collection and decision support tool to guide a user through the process of conducting a survey using the AWS. How the Applet actually works when loaded on a GPS unit and how to prepare the ArcGIS geodatabase required by the Applet are covered in detail in Chapter 3. The purpose of this section is to familiarize the user with how the Applet implements the AWS and to provide definitions of important terms necessary to understand the implementation (see Table 2-1). The AWS and Applet were developed to survey only one target NIS at a time.

The Applet guides the person performing the sampling, surveyor, through the process of conducting a survey using the AWS in three ways. First, it standardizes the information collected during a sampling session by providing menus, forms, and pick-lists of predefined values. Second, it has support tools and features that help the surveyor make key sampling design decisions, e.g., when to stop adaptively sampling. Lastly, once a target species has been found, the Applet performs the selection algorithm discussed in Section 2.1 to choose additional cells to be surveyed adaptively; referred to as an adaptive sampling session. It updates and displays the
sampling status of the cells in the survey grid, using the color scheme in Table 2-2 to aid the surveyor in navigation.

Table 2-1. Important Applet terminology and definitions.

<table>
<thead>
<tr>
<th>Term</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sampling Status or Scode</td>
<td>Used by the Applet to keep track of which cells have been sampled or surveyed and to determine the display color of each cell. Values and colors are in Table 2-2.</td>
</tr>
<tr>
<td>Plot Point</td>
<td>In the Applet, a surveyGrid feature is called a plot. The Plot Point is a point feature that indicates the starting location of a survey. It should be GPS captured in the first cell of the initial sample set.</td>
</tr>
<tr>
<td>Psp</td>
<td>The fixed probability of visiting a link between two neighboring cells once a target species is found and the patch pattern is ‘individual scattered plants.’</td>
</tr>
<tr>
<td>Initial Sampling Set</td>
<td>The primary sampling unit. It consists of a group of X-number of contiguous cells, where X is an integer greater than zero. It is also referred to as a transect.</td>
</tr>
<tr>
<td>Adaptive Sampling Session</td>
<td>Refers to the time spent and cells surveyed once a target species has been detected in one of the initial sample set cells.</td>
</tr>
<tr>
<td>Cell</td>
<td>The secondary sampling unit. It is a square polygon of fixed size.</td>
</tr>
<tr>
<td>Smax</td>
<td>Abbreviation for the maximum number of cells to sample in conjunction with each initial sample set or transect.</td>
</tr>
<tr>
<td>Amax</td>
<td>Abbreviation for the maximum number of cells to sample in an adaptive sampling session.</td>
</tr>
<tr>
<td>Survey Grid</td>
<td>A survey grid is a feature in the surveyGrid feature class. It consists of a fixed number of cells to the right and left of a transect as well as the cells making up the transect itself. During an adaptive sampling session, the Applet selects cells to randomly sample from those cells in the survey grid not already sampled. It is required by the Applet.</td>
</tr>
</tbody>

</tbody>
</table>
Being an ArcPad application, the Applet can update features stored in a GIS geodatabase, as well as create new features. To begin a survey, the surveyor creates a Plot Point. The Applet then displays a form allowing the surveyor to set the required AWS variables: $P_{sp}$, $S_{max}$, and $A_{max}$, as well as enter the names of the surveyors and target species. In addition, the surveyor can choose from two available options: Allow Random Additions and Constrain Random Additions. These options pertain to the selection algorithm used once an NIS is detected. Choosing the first option and not the second tells the Applet to implement the selection algorithm as described in Section 2.1. If the first option is not chosen, then no cells within the survey grid will be randomly selected when a link between neighboring cells is not selected to be followed. Choosing both options tells the Applet to implement the selection algorithm as described in Section 2.1 but limit the selection of any randomly chosen cells to just those cells either to the right or to the left of the current occupied cell, i.e., those cells in the same survey grid row as the occupied cell.

Once the variables and options have been entered, the surveyor can proceed with surveying cells from the initial sample set, which will be clearly displayed. After surveying each cell, the Applet’s updating tools can be used to change the sampling status of the cell. Each time a cell is updated, the display is updated as well. When a target plant is found, the Applet will require the surveyor to input values for the percent cover, density, and spatial pattern of the plants in the cell. Based on the data entered, the Applet will select and display additional cells to survey during an adaptive session. The selection process takes place on a cell by cell basis from among the cells not already surveyed. The Applet will also display labels indicating the order in which the cells selected for sampling should be surveyed.

Surveying adaptively in this manner continues until: (1) all cells selected by the Applet are surveyed, (2) $A_{max}$ is reached, (3) $S_{max}$ is reached, or (4) all the cells in the survey grid have been surveyed. If $A_{max}$ or $S_{max}$ is reached, the Applet will alert the surveyor with a pop-up window. If condition (1) or (2) is met, the surveyor continues surveying in this manner until all the cells in the initial sample set are surveyed.
3 Approach

This chapter describes the process necessary for a successful field session using the AWS Applet. It will guide you through the entire process from the creation of the necessary data, to the incorporation of the final sampled data into the geodatabase for monitoring and analysis. It assumes that you have correctly installed the Applet and have all the materials provided with the Applet installation files. If you have not installed the Applet, see Appendix A. Additionally, a summary of frequently asked questions is provided in Appendix B as a quick reference.

3.1 Prepare GIS data for ArcPad

This section describes how to prepare the required data for the Applet and transfer it to the GPS unit for use in the field. There are two steps in the process of data creation: (1) create and GPS-enable a geodatabase and (2) create features in the geodatabase’s feature classes. To simplify the geodatabase creation process, an empty geodatabase schema is provided with the Applet. Also, there is a customized ArcGIS tool provided to help create and attribute the required features in the geodatabase. These are also provided in the Applet installation files (also see Appendix C).

3.1.1 Create and GPS-enable the GIS sampling design geodatabase

The following steps show you how to prepare the geodatabase required for use with the Applet. It is assumed you have a copy of the geodatabase schema provided with the Applet. In the event that you do not have this schema, a complete description of the geodatabase is included in chart form in Appendix D to allow you to generate a geodatabase with all necessary feature classes, fields and attributes. To build your data with the existing schema:

Step 1. Copy the schema to your working directory

- Open ArcCatalog and in the table of contents navigate to the geodatabase titled AdaptiveWebGeodatabaseSchema.mdb you received with the Applet files
- Copy the geodatabase to your current working directory.
  - This manual will use the name AdaptiveWebGeodatabaseSchema.mdb for all examples. If
you choose to rename your copy of the database you will need to substitute that name, where appropriate, in future steps.

- Optional – Copy this original geodatabase and store it in a safe location as a template for future use

**Step 2. Define the geodatabase’s spatial reference**

Each feature’s spatial reference must be defined to work with ArcPad. You can choose to set the spatial reference by individual feature class or you can define it by feature dataset.

- In the ArcCatalog table of contents, expand the geodatabase:

![ArcCatalog tree view]

- Select the feature dataset **surveyGPSFeatures**. Set the coordinate system by right-clicking your mouse over the dataset and selecting **Properties**.
- Click the **XY Coordinate System** tab and select the coordinate system you prefer to use with your GIS data.
- Click **OK**. This sets the spatial reference for each feature class in the feature dataset.
- Repeat this process again for the feature class **surveyGrid**.

**Step 3. GPS-enable the geodatabase**

GPS-enabling the geodatabase allows data to be checked out for editing in ArcPad. **Note:** The **Trimble GPS Analyst** extension must be activated in ArcMap before the geodatabase can be enabled. To enable the geodatabase take the following steps:

- Right click on the **AdaptiveWebGeodatabaseSchema.mdb** file in the ArcCatalog table of contents and select **Properties**.
- Check the **GPS-enable geodatabase** button under the **Trimble GPS Analyst** tab.
Select all of the classes you will be updating with the GPS:

- Click OK.
- Select the appropriate transformation to convert your data from WGS_1984 into your chosen coordinate system and click OK.
  - All GPS data are collected in GCS_WGS_1984. If the coordinate system that you chose to use for your geodatabase is not GCS_WGS_1984, you will need to select a transformation method so that the data from the GPS can be correctly converted from GCS_WGS_1984 to your chosen coordinate system.
  - ESRI provides documentation of the many transformation methods with ArcMap so that you can choose the correct transformation for your area or consult a local GIS expert.
Note: At this point, ArcCatalog may display a warning indicating that the extents of the selected feature classes are outside the extent selected while GPS-enabling the geodatabase. This occurs because the geodatabase is empty. Click OK to this warning. In general, this will not cause a problem. However, you can prevent possible problems when you start to add features to feature classes in the geodatabase, by first zooming the data frame in ArcMap into a reasonable extent and scale for your intended field session. Load background data into ArcMap to find the correct location in the empty geodatabase, if you are unsure of the location and extent of your field sites when you first start ArcMap.

Step 4. Set GPS accuracy fields

The geodatabase schema for the GPS feature classes includes the attribute fields `ave_accuracy` and `worst_accuracy`. These fields will record the GPS accuracies for each feature you GPS-capture while in the field. By default the geodatabase is set not to record these values in the table, hence, you need to follow these steps to activate these fields for this purpose:

- In the ArcCatalog table of contents, right click on any one of the feature classes under the `surveyGPSFeatures` dataset.
- Select Properties and click on the Trimble GPS Analyst tab
- Use the drop down menus for Store Average Estimated Accuracy and Store Worst Estimated Accuracy to select the proper field in the geodatabase.
- Click OK.
- Repeat this process for each of the other feature classes under the `surveyGPSFeatures` dataset. Note: This does not need to
be done for the feature class **surveyGrid** because the features in this class will only be updated rather than created.

Your geodatabase is now GPS-enabled and ready for data preparation and check out.

### 3.1.2 Create features in the geodatabase

The Applet requires a populated **surveyGrid** feature class to function properly. A tool for use in ArcMap has been provided with the Applet to simplify the creation of the **surveyGrid** features. The **Survey Grid Builder** tool uses a transect line feature to create a set of equal area polygons, i.e., a **surveyGrid** feature, see Figure 3-1. The individual polygons, referred to as cells, are squares whose side lengths are referred to as cell size. For example, a cell size of 10 m would produce a cell whose length and width equal 10 m and area equal to 100 $m^2$. A feature class of transect lines is required for input into the tool. These transects can be created via any process you chose, but the feature class **MUST** be in the same coordinate system as the features in your geodatabase. The **Survey Grid Builder** tool will build a **surveyGrid** feature corresponding to each transect, hence including several line features in a single feature class will save time and effort in the construction of the **surveyGrid** features.

Before proceeding, you should create transect line features to use with the tool. The tool will accept transects of any length. If a transect’s length is not a multiple of the cell size, however, there will be a length of transect that extends beyond the **surveyGrid** feature. For example if you choose a cell size of 10 m and a transect’s length is 79 m, there will be a 9 m section of the transect extending beyond the **surveyGrid** feature (see Figure 3-1). To avoid confusion in the field, it is best to ensure all transect lengths are multiples of cell size.
Step 1. Add the tool to ArcMap

- Locate the folder supplied with the Applet called AdaptiveSamplingTools. This folder contains the toolbox, tool, and source script for the tool.
- Optional: Copy this folder and all of its contents to a secure location for future use.
- Open ArcMap.
- Right click in the ArcToolBox window and click Add Toolbox.
- Navigate to the file Adaptive Sampling Tools folder provided with the Applet.
- Select Adaptive_Sampling_Tools toolbox and click Open.

The Adaptive Sampling Tools toolbox should now be added to the ArcToolBox.

Step 2. Use the Survey Grid Builder to create the surveyGrid features

The Survey Grid Builder tool uses the input variables Cell Size, TransectLine Feature Class, Survey Grid Feature Class, and Number of Cells to create a surveyGrid feature surrounding each transect line. All but the number of cells has been discussed previously. The “number of cells” variable defines the width of a surveyGrid feature; it represents the number of cells to the right or to the left of the group of “center” cells that the transect line bisects (see Figure 2-1). A surveyGrid feature width is given by the following formula:
Survey Grid Width = (2*Number of Cells)*Cell Size + Cell Size

To create survey grid features in the surveyGrid feature class:

- Add the AdapativeWebGeodatabaseSchema.mdb and your transect line layer to ArcMap.
  - This will make the surveyGrid feature and line layer available in the drop down menus in the tool.
- Double click the Survey Grid Builder script tool in the Adaptive Sampling Tools Toolbox.
- Fill in the values for the four tool variables.
- Click OK.
  - If you have a large number of transects or a small cell size, the tool will take several minutes or longer to build all of the surveyGrid features.

Step 3. Attribute the cells in each of the surveyGrid features

Table 3-1 shows the possible Scode and Status values for the survey grid cells. Open the surveyGrid attribute table. Notice the Survey Grid Builder tool has populated all the survey grid cells with a Scode of 2 and the Status field with Not Sampled. It is, therefore, only necessary to assign values of -1 to the desired initial sample set, which is the set of cells intersecting your transect lines. You will also notice the Survey Grid Builder tool has attributed the fields col and row; therefore, the only other field you need to attribute for each cell is LHV. Updating the Scode, Status, and LHV fields can be accomplished using any method — such as an edit session — but must be done for the Applet to function correctly.
Table 3-1. Values for Scode and status for each cell in a surveyGrid feature.

<table>
<thead>
<tr>
<th>Scode</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>-9</td>
<td>Not Sampleable</td>
</tr>
<tr>
<td>-1</td>
<td>Initial Sample Set</td>
</tr>
<tr>
<td>0</td>
<td>Sampled/Absent</td>
</tr>
<tr>
<td>1</td>
<td>Sampled/Present</td>
</tr>
<tr>
<td>2</td>
<td>Not Sampled</td>
</tr>
<tr>
<td>3</td>
<td>Need to Sample</td>
</tr>
</tbody>
</table>

Figure 3-2 shows a finished surveyGrid feature along with a roads layer. The initial sample set is shown in purple. Your data should look similar when finished.

3.1.3 Add additional background reference data

Along with checking out data from the geodatabase, other GIS data can be copied out as background or reference data for use in ArcPad.

**Step 1. Add any background reference data needed to complete the survey**

This could include roads, streams, or aerial photographs that will help you navigate while in the field.

**Step 2. Save your ArcMap document**

You will use this .mxd to check out and check in geodatabase layers and copy out all other layers for use in ArcMap using the Trimble GPS Analyst.
Once you have built and attributed all of the features required, layers in your geodatabase are ready to be checked out for use in the field.

3.2 Check out data for ArcPad

This section will guide you through the process of checking out data from your GPS-enabled geodatabase and transferring it to a GPS device for use in the field. Here you will check out all of the feature classes required by the Applet to function, as well as any layers useful for navigation or reference as background layers. This manual assumes that you have the proper program files for installation of the Applet on your GPS unit and that the Applet is correctly installed on the unit. If the Applet is not currently installed on your GPS unit, see Appendix A and Appendix B.

Step 1. Get the appropriate buttons

Before beginning the data check out process, ensure that the correct buttons are present on the Trimble GPS Analyst toolbar. The buttons required for this process are (1) Get Data for ArcPad and (2) Check in ArcPad Shapefiles and GPScorrect SSF.

If you do not find the buttons on the toolbar, they must be added before beginning data check out. To do this:

- Right click on the Trimble GPS Analyst toolbar.
- Scroll through the list and click on Customize.
- Select the Commands tab.
- Under the Categories heading, select Trimble GPS Analyst.
- Select the tools under the Commands heading and drag them onto the Trimble GPS Analyst toolbar.
  - The Check in ArcPad button will be grey and unavailable on the toolbar until data have been checked out and a GPS editing session has been started.
  - To avoid confusion, unnecessary buttons can be dragged off the toolbar if they are not needed.
- When you have added the necessary buttons, click Close.
Step 2. Connect the GPS unit to the computer using ActiveSync

- Connect using the method to which you are accustomed.
  - A Guest Partnership is the recommended connection method.

Step 3. Check out data

- Open the Arc Map .mxd containing your geodatabase that you saved in Step 2 of Section 3.1.3.
- Zoom to the extent of the data you wish to check out.
  - It is strongly recommended that you set the extent to a single survey grid feature and only check out one survey grid per check out session. By doing so, ArcPad will run much faster. ArcGIS allows multiple check outs from a geodatabase and you can load multiple check out sessions on your GPS units to use in ArcPad at one time. Hence, if you have several survey grid features in your surveyGrid class and check them out separately, it will not cause any problems in either ArcPad or your geodatabase.
  - It may be helpful to create a bookmark at each survey grid for future reference or checkout.
- Click the Get Data icon to access the menu for data selection:
Select all the layers that you wish to display in ArcPad, including background files, and click Next:

![Select layers for ArcPad](image)

Select all the layers to checkout for GPS editing in ArcPad and click Next:

![Select layers for checkout](image)

Verify that the radio button next to **The current display extent** is selected. This button is located under the question **What spatial extent do you want to get data for?**

- This limits the amount of information that will be transferred onto the GPS unit.

Specify a name and a location on your desktop to save the checked out data.

Verify that the **Create an ArcPad Map** checkbox is selected.

Click Finish.
Step 4. Transfer checked out data to the GPS unit

- Open the folder where you specified to have your data placed during the check-out process.
  - Rename the ArcPad .apm file to a more descriptive name.
- Delete the .sbn and .sbx file extensions from the **surveyGrid** files.
  - This allows ArcPad to run much faster and is strongly recommended.
  - Do not delete these files for any other layers, only the **surveyGrid**.
- Choose a location on the GPS unit and copy the data folder to the GPS using **Copy** and **Paste**.
  - It is recommended to copy your data to the Mobile Device Screen of your GPS unit or to the default path used by ArcPad.
Step 5. Customize the configuration file.

Before going into the field, you will want to customize the Applet’s configuration file, AdaptiveSampling.config. The configuration file sets variables required by the Applet to the appropriate layer names in the user’s geodatabase and specifies possible values for certain fields such as targeted species or surveyor names. Specified values for certain fields will show up in the form of pick lists when the Applet is used. While still connected to the GPS unit with active sync:

- Use Windows Explorer to navigate to the folder in the Mobile Device window that contains the Applet files
- Copy the AdaptiveSampling.config file onto your computer and update the necessary fields:
  - Fill in all pick lists with the desired possible values.
  - Verify that the layers that were checked out from the geodatabase are properly specified in the AdaptiveSampling.config file, and update the file names as necessary. If the feature class layer’s names in the AdaptiveSampling.config file for the variables are not the same as the feature class layer names that were checked out from the geodatabase, the Applet will not function correctly. In the AdaptiveSampling.config file, the two layers important for the Applet to function are PlotLayer and GridLayer. For example, by default the GridLayer = surveyGrid. If, however, your surveyGrid, for example, is named mySurveyGrid, then the variable GridLayer should be set equal to mySurveyGrid. If you used the schemas provided to create your geodatabase, no variables relating to the geodatabase should need to be changed. See Appendix B for more information.
- Replace the AdaptiveSampling.config file in the Applet file with the updated file

3.3 Conduct a survey

After you have checked out your data and transferred them to your GPS unit, start ArcPad and make sure you can open the .apm file. This section will guide you through the process of carrying out a survey using the AWS Applet. The steps assume you have opened the appropriate ArcPad map (.apm) containing the GIS data for data collection or update, activated the GPS receiver, and verified the GPS status.
**Step 1.** Move to the first cell in the initial sample set and record a start point using the **Capture Plot Point** button (the Applet refers to a surveyGrid feature as a plot). Enter or choose values for **Target Species**, **Surveyor1**, **Surveyor2**, **Smax**, **Amax**, and **P_sp**. Also, check the box next to **Allow Random Additions**, if you want the Applet to choose and display random cells to survey when appropriate. If you want these random selections to be constrained to just the right or left of the cell containing the target species, check the box next to **Constrain Random Additions**. The remaining steps assume random selections are requested and are not constrained to the left or right of an occupied cell.

**Step 2.** Move to each of the cells in the initial sample set looking for the target plant species; starting with the one where you recorded the start Plot Point in Step 1. If the target species is not found within a cell or for some reason you are unable to survey the cell, use the **Update Grid Cell** button to update its sampled status to **Sampled/Absent** or **Not Sampleable**, respectively. If the target species is found within a cell, use the **Update Grid Cell** button to update its sampled status to **Sampled/Present**. In this case, you will also need to fill in values for the **Per.Cover**, **Patch Density**, and **Patch Pattern**. Click **OK**. The Applet will chose and display the cells you need to sample adaptively. These cells will be displayed orange with “0” labels (see Figure 3-3). An adaptive sampling session has now started, and the Applet will keep track of the number of cells sampled adaptively.

**Step 3.** Continue sampling the cells labeled “0” looking for more target plants and using the **Update Grid Cell** button to update each cell’s sampling **Status**. Whenever a cell’s **Status** is updated to **Sampled/Present**, the Applet will choose additional cells to sample adaptively and will label each new set of cells associated with an occupied cell with a consecutive integer 1, 2, ..., 4 etc. corresponding to the order the occupied cells were encountered. You should, but are not required to, sample all cells in the order they are labeled.
Figure 3-3. Example showing Applet display during sampling. This illustration shows how the Applet will generate successively labeled levels of adaptive cells for each presence documented. The first presence along the initial sample set generates ‘0’ cells, the next ‘1’ cells, and on until the adaptive limit is reached or no more plants are found. Here sampling began with an absence in the initial sample set and the second cell was sampled as a presence, initiating adaptive sampling.

**Step 4.** Continue with the adaptive sampling session until either the maximum number of cells sampled adaptively, $A_{\text{max}}$, is reached or you have run out of cells to adaptively sample, i.e., orange cells. In the first instance, the Applet will display a window informing you $A_{\text{max}}$ has been reached and asking you if you wish to continue. Select No. The Applet will automatically reset the counter for number of cells sampled adaptively to zero, erase the labels, and change the color of the cells that were not yet sampled back to blue. In the second instance, you will have to use the **Reset Counter** button, as described below, to achieve the same effect.

**Step 5.** After sampling all of the adaptive cells, move back to the next cell in the initial sample set.

**Step 6.** Continue with Steps 2–5 until all the cells in the initial sample set have been sampled or the maximum number of cells to be sampled within the **surveyGrid** feature, $S_{\text{max}}$, has been reached. For correcting possible errors made during the sampling process, see “2)” in the next step.
Step 7. Save and close your ArcPad map and move to the next surveyGrid feature.

Resetting the Applet’s counters

1) Running out of cells to sample adaptively. If, during an adaptive sampling session, all of the additional cells chosen by the Applet are sampled before $A_{\text{max}}$ is reached, the counter that keeps track of the number of cells sampled adaptively needs to be set to zero. To do this, access the Reset Counters form from the menu under the Capture Plot Point button. Reset the $A_{\text{max}}$ counter and the Labels to 0, and Weed Found to False.

![Reset Counters](image)

2) Correcting a mistake. During the course of a survey, if a cell is mistakenly updated with the wrong value and needs to be changed, the steps below must be followed to correct the mistake and avoid discrepancies with the Applet’s counters for $A_{\text{max}}$ and $S_{\text{max}}$. For additional help with the Applet’s buttons, see Appendix E or Appendix F.

Two different updating mistakes can be corrected while conducting a survey; either (a) updating a cell’s sampling Status to Sampled/Absent when, in fact, there was a target species present or (b) updating a cell’s sampling Status to Sampled/Present when there was no target species present. However, because these mistakes can occur while sampling a cell in the initial sample set or while carrying out an adaptive sampling session, there are actually two cases to consider.

Case 1. A mistake made while sampling an initial sample set cell
If you need to change a cell Status from Sampled/Absent to Sampled/Present, use the Update Grid Cell button and change the value from absent to present. The counters will automatically adjust for the error and no other steps are required.
If you need to change a cell **Status** from **Sampled/Present** to **Sampled/Absent**, use the Update Grid Cell button and change the value to **Sampled/Absent**. Once the cell is updated, access the **Reset Counters** form from the menu under the **Capture Plot Point** button and reset the **Amax counter** to 0 and **Weed Found** to **False**. In this situation, the Applet does not automatically correct the sampling **Status** of the cells it selected to be adaptively sampled. This must be done manually using ArcPad edit tools. By changing the sampling **Status** back to **Not Sampled**, these cells become available to the selection process again.

**Case 2. A mistake made while sampling cells during an adaptive sampling session**

If you need to change a cell from **Sampled/Absent** to **Sampled/Present**, use the Update Grid Cell button and change the value to **Sampled/Present**. Also, access the **Reset Counters** form from the menu under the **Capture Plot Point** button and decrease the **Amax counter** by one. Nothing else needs to be done.

If you need to change a cell **Status** from **Sampled/Present** to **Sampled/Absent**, use the Update Grid Cell button and change the value to **Sampled/Absent**. Nothing else needs to be done to avoid errors in the Applet’s counters. In this situation, the Applet does not automatically correct the sampling **Status** of the cells it selected to be adaptively sampled. This must be done manually using the ArcPad edit tools. By changing the sampling **Status** back to **Not Sampled**, these cells become available to the selection process again.

### 3.4 Check in data from ArcPad

After completing a successful field session, it is necessary to check your survey data back into the geodatabase. This section will guide you through the process of data check in. Once your data are successfully checked in, they are ready for post-processing and further analysis or other final use. **Note:** Data check in and check out transactions are both PC specific; you must use the same computer to both check out and check in the data.
Step 1. Connect the GPS unit to the computer using ActiveSync

- Connect using the method to which you are accustomed.
  - A **Guest Partnership** is the recommended connection method.

Step 2. Check in data

- Transfer the data folder from the GPS back to the computer using Windows Explorer.

You want to replace the file that was originally checked out with the new updated file. By replacing the original folder, the Trimble GPS Analyst will know where to find your updated information.

- Open Arc Map and the map document (.mxd) containing your geodatabase.
- Start a GPS edit session by select **Start GPS Editing** under the **Trimble GPS Analyst** toolbar.
  - This will simultaneously start an ArcMap edit session.
  - This also activates the **Check in ArcPad shapefiles** and **GPS correct SSF** button.
➢ Use the **Check In Data** button to select the layers that need to be checked into your geodatabase. Select all the layers that you checked out for editing
➢ Click **OK** to begin the import process

Once the import is finished you are ready to post process your data using the **Trimble GPS Analyst** toolbar.
References

Appendix A: Requirements and Installation

Requirements

Operating system and GPS unit

- ArcPad 7.1 or greater
- GPS unit with Windows Mobile 6 or greater installed
- This Applet was tested on and recommended for use on Trimble GPS units.

Installation

Configuration file

There is a configuration file with the Applet called WebSampling.config. This is a customization file for the Applet which stores information required by the Applet and can be edited in a text editor before being uploaded to the device. An example configuration file follows:

```
Surveyor1=Bruce,Leroy,Joe,Ted,Jeff *Defines pick list for surveyor 1
Surveyor2=Bruce,Leroy,Joe,Ted,Jack *Defines pick list for surveyor 2
TargetSpecies=Bromus tectorum,Cirsium arvense,Linaria dalmatica pratense *Defines pick list for target species
Smax=10 *Defines maximum number of sampling units per plot
Amax=4 *Defines maximum number of sampling units to sample adaptively
Psp=.7 *Defines the constant probability of surveying one of the eight adjacent neighboring cells
PlotLayer=plot *Defines the plot layer name for the applet to use
GridLayer=surveyGrid *Defines the survey grid layer for the applet to use
CurrentSurveyor1=Leroy *Defines current surveyor 1 in ArcPad – written by applet
CurrentSurveyor2=Joe *Defines current surveyor in 2 ArcPad – written by applet
CurrentPlotID=CobbleCreek *Defines current Grid plot ID – written by applet
CurrentTargetSpecies=Cynoglossum officinal *Defines current target species – written by applet
AllowRand=True *Defines if random selections are allowed by Applet
ConstRand=*Defines if random selections are constrained to current grid row.
```
Gridsize=10 *Defines grid cell size

Fields in **bold** above are required values. The variables **PlotLayer** and **GridLayer** refer to shapefiles checked out from the geodatabase for use with the Applet. If you have renamed the feature class layers prior to checkout, you will have to modify the names here so that the Applet knows which layers to use for each variable. For example, using the above list, the Applet will look for a GridLayer named surveyGrid. If, however, the survey grid feature dataset name was changed in the geodatabase to mySurveyGrid, then the variable GridLayer should be set to GridLayer=mySurveyGrid. **TargetSpecies** and **Surveyors** are pick lists for the Applet to use and must be populated prior to using the Applet. This file should be updated before taking your data to a survey. Either change the configuration file before transferring it to the GPS unit, or once the files are all transferred to the unit, copy it to your computer, change the values that need to be changed, and then copy it back to the unit, overwriting the old configuration file.

**Applet**

To install the Applet, copy all files contained in the Applets folder to the Program Files/ArcPad/Applets folder on the mobile device. The Applet is installed by ArcPad on startup. So if ArcPad is running on the device, you will need to restart ArcPad after the files are copied to the mobile device.
If the application is installed correctly a new tool bar will appear within ArcPad.

**Note:** When the Applet initially loads the configured data files, it writes new forms (apl files) for the application to use. To verify the files have been updated correctly, the word “updated” will appear in the comments section of layers properties in ArcPad. In the event these files need updating, clear the word “updated” and save and close ArcPad. When the file is loaded again it will be updated.
Appendix B: Frequently Asked Questions

Where can I get the Applet software? The software is available from the Montana State University, Weed and Invasive Plant Ecology and Management Group website: http://weedeco.msu.montana.edu/rangewildland/index.html.

What is the benefit of using an adaptive sampling method? Adaptive sampling is an efficient way to locate populations of invasive plants that are rare but spatially clustered. Adaptive sampling, as guided by the Applet, will help the surveyor focus their surveying efforts in areas where invasive plants are found.

In what scenarios is the method expected to provide benefits over other standard approaches? This adaptive sampling method provides a benefit when the invasive plants to be surveyed are relatively rare but clustered across the landscape. When the detection of one population triggers the launch of adaptive sampling, additional effort is spent adaptively searching for other populations in the vicinity of the found population. If, however, populations are ubiquitous across the landscape, adaptive sampling will provide no benefit because populations will be encountered regardless and adaptive sampling will be excessively slow.

Can this method be used to survey more than one species at a time? No, this method was developed with the intent of sampling a single species at a time. Attempting to record multiple species will affect the Applet’s ability to select random cells to be sampled and will negate the results of the survey.

How do I install the Applet on a GPS unit? Appendix A in this manual describes the process of installing the Applet on a Trimble GPS unit. It is as simple as copying files into the correct directory on your mobile unit.

Will the Applet run on any GPS unit? This method was developed for Trimble’s GeoExplorer series of GPS unit and is as yet untested on other platforms. While it may run on other platforms, the current testing
has all been done on GeoExplorer 2008 units and using this Applet on another platform may yield less than satisfactory results.

**How do I start a new sampling session?** When starting a new transect or when finished with an adaptive sampling session, a new adaptive sampling session will begin with the recording of a new Present value.

**How do I record the presence of an invasive plant?** Invasive plant presences are recorded by simply clicking the Update cell icon and recording a Present value in the data entry table along with all required attribute values.

**What do I do after I record the first presence along a transect?** After recording a presence along a transect, the Applet will generate additional cells to be sampled but not on the transect. Following the *Conduct a Survey* methods prescribed in section 3.3 of the user’s manual provided with the Applet, begin sampling additional cells.

**What if no invasive plants are present in the cell identified for adaptive sampling?** Simply mark the cell in question as absent and continue sampling the transect in accordance with section 3.3 *Conduct a Survey*.

**What do I do if I see a population of invasive plants that are not in a transect cell that I am supposed to sample?** Presences should be recorded only if they occur within the cell to be sampled whether that is a transect cell or an adaptively selected cell. Recording information from neighboring cells will bias the results of the survey.

**What if I sample the entire transect and no invasive plant presences are recorded?** The sampling session is over.

**What do I do when the Max Search Area has been reached?** If an initial Adaptive Plant Patch is identified and the boundary extends beyond the demarcated Max Search Area polygon, no adaptive sampling should take place. If, however, the initial polygon falls within the Max Search Area polygon, adaptive sampling will take place until all adaptive cells have been sampled within the Max Survey Area. See section 3.3 for detailed illustrations on how to conduct a survey.
What do I do when Amax has been reached? When the number of cells sampled equals the number set for Amax, adaptive sampling is finished. When the Applet asks if you would like to continue, click No and return to the transect for additional sampling.

What do I do when the Max Survey Area has been reached? No sampling of any kind should take place beyond the boundary of the Max Survey Area. If a patch is being delineated that extends beyond this boundary, the surveyor should instead follow the boundary of the Max Survey area rather than the actual patch boundary. No adaptive sampling should ever be done outside of this polygon.

What do I do when Smax has been reached? If Smax is reached, then the total number of cells that you wish to sample has been reached and the survey is finished.

How do I choose appropriate values for Smax, Amax, and Psp? These values will be specific to the species and landscape being surveyed and the goals of the survey. Therefore, a simple answer cannot be provided in this document. In general terms, however, Smax is based on time considerations and the total amount of data needed. Amax could be matched to the dispersal distance of the target species, and Psp could be related to the local habitat variability.

If I made a mistake in entering Present/Absent values, how do I edit them? Consult manual section 3.3 “Correcting a mistake” for the proper method to change values. In many cases entering an incorrect value can be changed without additional consideration by simply changing the value. However, there are occasions where it is necessary to update the sampling counters when a change is made. Section 3.3 will guide you in determining whether additional changes must be made.

What happens if I accidentally close ArcPad during the survey? In many cases, ArcPad saves any edits/changes to the data without presenting a “Save Data” menu option. It has been observed that, if ArcPad is accidently closed, data are not lost. However, it is always best to save data regularly.
How do I save the file after the survey has been completed?

*When ArcPad is closed, it will present a “Save Data” menu option. Affirm save data and close.*
Appendix C: File Reference

The following files and folders, described below, are included for use with the AWS Applet:

- A folder called AdaptiveSamplingTools
- A folder called Documentation
- A folder called Adaptive_Web_Applet
- An empty geodatabase schema in the correct format containing all required fields and attributes.

AdaptiveSamplingTools

This folder contains an ESRI tool box file called Adaptive_Sampling_Tools.tbx as well as the script to be used for the construction of data in the geodatabase. To access the tool this script belongs to, open ArcMap and right click in the Toolbox window, choosing the menu Add Toolbox. Correctly define the location of the Adaptive_Sampling_Tools.tbx at the location in which you have chosen to keep the .tbx file. This location can be within the AdaptiveWeb folder as provided or at another location. Be sure to keep the PYTHON script file in the same folder as the .tbx file. If they are separated, the tools stored path will not be correct and the tool will not work. Should this happen, verify that the script path is correct. Once the toolbox is added to the toolbox window, the Survey Grid Builder tool will appear. Double click on this tool to access its functionality.

Documentation

This folder contains all of the documentation that was provided with the Applet. It includes users’ guides, tips, and methods for the all of the processes that must be completed to utilize this method of sampling and to properly prepare data for use by the Applet. This documentation goes step by step through the majority of processes required by the Applet. It is recommended that this documentation be read before using the Applet and kept available for future reference.
**Adaptive_web_applet**

Contains all of the files required to run the Applet on the GPS unit. From this folder, **Copy** and **Paste** the files into the Program Files/ArcPad/Applets folder on the GPS.

**Applet2GeodatabaseSchema.mdb**

This is the empty geodatabase that has been prepared for this Applet. It contains all of the correct layers, fields, and attributes required for the Applet to function properly. It is recommended to make a backup of this .mdb before making any changes. If the original is lost, or for any reason it becomes necessary to build a new geodatabase, a table is provided in the documentation illustrating the proper layout and required fields of the geodatabase.
## Appendix D: Geodatabase Design

### Personal Data Base Design

**Geodatabase Name:** User Defined  
**Geodatabase Domain:**

Appendix E: Applet Operation

Starting the Applet

The Applet is automatically loaded by ArcPad when the application is started. A new tool bar will appear in when the Applet is properly installed.

Capture plot point

Plot Points are created to define start of transects, click the Capture Plot Point button to create a starting point for a plot (right). If the GPS is active, the data collection form is shown (left). If the GPS is not active, a dialog will appear asking to turn it on.

When creating a Plot Point the Smax, Amax, Allow Random Additions, and Constrain Random Additions values are set for the current plot and stored until another Plot Point is created.

Reset counters

The submenu under the create Plot Point button allows the user to reset the Current Smax, Amax, and Label counters and the indicator for Weeds Found. This form is used if a surveyor finishes a plot before the
**Amax** counter has been reached, or if a mistake is made in marking a grid cell.

### Update grid cell

The Update grid cell button is used to update the current grid cell based upon the surveyor's current GPS location. With an active GPS location, click this button to select the grid cell based on the current GPS location and display the survey grid form.

Updating the grid changes the color of the grid cell to visually indicate the status of the grid location. There are five different values for the grid cells: 0 = Sampled/Absent (red); 1 = Sampled/Present (green); 3 = Need to Sample (orange); 2 = Not Sampled (blue default value); and -9 = Not Sampleable.

When a cell is marked as **Sampled/Present**, the additional values **Target Spc.**, **Per. Cover**, **Patch Density**, and **Patch Pattern** are required values. Marking a cell as Sampled/Present launches the random selection procedure to mark additional cells that need to be sampled (orange). Below are examples of what the selection procedure will produce if **Allow**
Random Additions is checked (left) and if Constrain Random Additions is checked (right).

11. DISTRIBUTION / AVAILABILITY STATEMENT
Approved for public release; distribution is unlimited.

12. SUPPLEMENTARY NOTES
The most cost-effective and feasible strategy for managing any recently established non-native invasive plant species (NIS) is early detection and rapid response. However, conventional sampling designs can be inefficient and costly to implement when sampling early phases of invasion. Adaptive sampling designs were specifically developed as alternatives to conventional sampling to take advantage of the rarity and clustered nature of many biological populations. One class of adaptive sample designs is adaptive web sampling, which provides a balance between increasing sampling in the immediate proximity of an already detected patch and sampling farther away from the detected patch to locate more distant satellite patches. This balance makes adaptive web sampling well suited for mapping NIS in early invasion phases when invasive populations are rare and locally clustered. Adaptive web sampling is also more flexible than other adaptive designs because the amount of sampling effort allocated to adaptive selection can be based on local factors. This manual describes an adaptive web sampling design and a user-friendly GPS interface developed to aid implementation of the sampling design in the field. The GPS user interface is a customized application developed for ESRI’s (Redlands, CA) ArcPad® mobile geographical information system (GIS) software.
