**ABSTRACT**

Objectives. Patients with metastatic breast cancer identified as human epidermal growth factor receptor 2 (HER2)-positive (HER2+) routinely receive the anti-HER2 antibody trastuzumab plus chemotherapy. 64Cu-DOTA-trastuzumab/PET-CT has high tumor detection sensitivity in HER2+ patients [Bading, et al., JNM 2012;53 (Suppl 1):229P]. We are also imaging HER2- patients and present an initial comparison of tumor uptake between the two groups. Methods. Patients with biopsy-proven HER2+ (n=9) or HER2- (n=4) metastatic breast cancer who had not received anti-HER2 therapy for ≥ 4 mo were given trastuzumab i.v. (45 mg, to reduce liver uptake) prior to i.v. injection of 64Cu-DOTA-trastuzumab (364-512 MBq). PET-CT scans were obtained at 21-25 h (Day 1; 3-4 bed positions, 20 or 15 min each) and 47-49 h (Day 2; 1-2 bed positions, 60 or 30 min each) over fields of view based on recent (5-17 d prior) 18F-FDG scans. Tumor uptake was measured as body weight-normalized SUV [maximum voxel (SUVmax) and whole-tumor (SUVwt)]. Results. For Day 1, mean SUVmax was 77% higher in lesions from HER2+ vs HER2- patients [(n, mean, median, sd, range) = (57, 7.8, 6.6, 4.3, 2.4-22.5) and (25, 4.4, 4.1, 1.1, 3.0-6.8), respectively; p<1x10^-6 by 2-tailed t test on log-transformed data]. Day 2 and SUVwt results were qualitatively the same as Day 1 SUVmax. Using median Day 1 SUVmax for a given lesion site and patient (pt), analysis for the two most common sites showed: bone [HER2+ (6 pts) 54% > HER2- (3 pts), p<0.05] and lymph nodes [HER2+ (8 pts) 54% > HER2- (3 pts), p<0.05]. Conclusions. Tumor uptake of 64Cu-DOTA-trastuzumab was higher on average in HER2+ vs HER2- patients, with significant intra-group and intra-patient variability. Our observations suggest that, by 1 d post-injection, uptake reflects binding of the radiotracer to HER2. Intra-group and intra-patient heterogeneity may have been due to variations in tumor HER2 expression, and/or other factors (blood clearance, blood-tumor transport, etc.) that influence uptake of 64Cu-DOTA-trastuzumab.

1. INTRODUCTION:
The term “breast cancer” encompasses a number of different diseases that are clinically defined by hormone receptor status and HER2 expression. HER2 has tyrosine kinase activity that results in intracellular signaling and activation of genes for cell growth and survival. Women whose cancers overexpress the HER2 protein have a distinct natural history and are candidates for treatment with trastuzumab. Trastuzumab is at humanized IgG-1 antibody that binds to the ectodomain of HER2. When combined with chemotherapy, trastuzumab significantly improves the survival of women with both early stage and advanced disease. The pathologic assessment of HER2 status is made on the primary tumor or metastatic foci. Generally this is small sampling of a portion of one tumor and many not reflect the entire tumor or other sites of disease. HER2 overexpression and candidacy for trastuzumab is defined as 3+ staining by immunohistochemistry (IHC) or gene amplification by fluorescence in situ hybridization (FISH). In the randomized trials of HER2-directed therapy, a consistent group of women enrolled were actually HER2 negative on central pathology review. In both the adjuvant and metastatic settings, those who receive HER2 directed therapy did better. This suggests that HER2-directed therapy should be expanded to include some women with HER2 negative breast cancer.

The impact of HER2 directed therapies on disease outcome is considerable. However, the cost, potential risk of cardiac toxicity, and inconvenience of intravenous administration make it imperative that an accurate assessment of HER2 be made in all women with breast cancer. We hypothesize that a functional assessment of HER2 will be more accurate than pathologic assessment.

Positron emission tomography (PET) provides a non-invasive way of studying tumor location, metabolic functions, and response to therapy. In breast cancer, PET imaging is used to stage women with advanced disease and to assess response to chemotherapy and endocrine therapy before tumor regression can be documented on clinical or radiological exam. The ability to identify patients who may benefit from systemic therapy is critically important to the quality of life of patient; toxicities from ineffective therapies are prevented and medical costs are contained.

Radiolabeled trastuzumab has effectively been used to study HER2 positive breast cancers in animal models and in humans, in part because trastuzumab has a high rate of internalization, which results in trapping of radiometals within the cell. 64Cu-DOTA-trastuzumab, first developed at City of Hope, accurately identified HER2 positive breast cancer in nude mice bearing an MCF7 HER2 overexpressing xenografts. Others have been unable to demonstrate the utility of trastuzumab-based PET imaging. Because normal tissues that express HER2 will bind the radiolabeled (hot) antibody, administration of a “cold dose” of antibody might improve the tumor specificity of the radiographic image. None of the studies that have utilized radiolabeled trastuzumab as an imaging agent have consistently administered a large “cold dose” of trastuzumab prior to radiographic imaging. We hypothesize that the dose of “cold antibody” is critical for image quality. We believe that too high a dose of “cold antibody” will reduce tumor uptake and thereby compromise the quality of the radiographic image.

The primary objective of this pilot study is to determine the optimal dose of cold antibody required for 64Cu-DOTA-trastuzumab PET to produce a high image quality in women with metastatic HER2 positive breast cancer. In addition, we will assess the impact of the...
cold antibody dose on cardiac uptake of $^{64}$Cu-DOTA-trastuzumab. To establish the optimal dose of cold antibody, we will image women with documented metastatic breast cancer with 3 different protein (trastuzumab) doses - 5 mg, 50 mg, and 4 mg/kg.

Once we have established the optimal dose of "cold antibody" the secondary objective was to correlate tumor uptake of $^{64}$Cu-DOTA-trastuzumab PET with the degree of immunopositivity of HER2 in women with metastatic disease. Women with metastatic breast cancer that is 1+, 2+, or 3+ positive by IHC assessment of HER2 will undergo a $^{64}$Cu-DOTA-trastuzumab PET imaging. We will correlate the standardized uptake values (SUVs) of tumor identified on $^{64}$Cu-DOTA-trastuzumab PET with the degree of positivity of HER2 by FISH.

We believe that functional imaging with $^{64}$Cu-DOTA-trastuzumab PET has the potential to improve the accuracy of HER2 assessment in vivo. Future studies will address tumor biomarker assessment with serial $^{64}$Cu-DOTA-trastuzumab PET and $[^{18}\text{F}]$FDG/PET before and after treatment with trastuzumab to determine which patients are likely to benefit from the drug.

   Functional imaging
   HER2 positive

3. **OVERALL PROJECT SUMMARY:**

   **Aim 1:** Determine the dose of pre-administered cold antibody that optimizes image quality of $^{64}$Cu-DOTA-trastuzumab PET without increasing the radiation dose to the heart in women with metastatic HER2 positive breast cancer.

   **Study 1:** Eight women underwent $^{64}$Cu-DOTA-trastuzumab PET and $^{18}$F-FDG/PET before and after treatment with trastuzumab. Initially we planned to image 15 women who would receive 3 different pre-administered doses of trastuzumab. The two women who received the lowest dose (5 mg) had poor image quality compared to those receiving 50 mg. Communications with investigators who preadministered larger doses (4 mg/kg) also had poor image quality. We anticipated that the higher dose may have resulted in binding to the tumor receptors precluded uptake of the radiolabel. Therefore we discontinued this study with 8 patients accrued

   **Findings as a result of Study 1:**
   1.) $^{64}$Cu-DOTA-trastuzumab PET is feasible
   2.) We identified no significant cardiac uptake on $^{64}$Cu-DOTA-trastuzumab PET
   3.) We found a high degree of concordance between $^{18}$F-FDG PET and $^{64}$Cu-DOTA-trastuzumab PET.
   4.) A preadministered dose of 45 mg cold trastuzumab resulted in a 75% decrease in uptake of $^{64}$Cu and improved image quality. This became the standard for subsequent $^{64}$Cu-DOTA-trastuzumab PET imaging.

   **Aim 2:** Determine whether tumor uptake on $^{64}$Cu-DOTA-trastuzumab PET correlates with tumor expression of HER2 in women with metastatic disease.

   **Study 2:** Ten women whose HER2 status was 1+, 2+, or 3+ underwent $^{64}$Cu-DOTA-trastuzumab PET and $[^{18}\text{F}]$FDG/PET before and after treatment with trastuzumab. We
Findings as a result of Study 2:
1.) $^{64}$Cu-DOTA-trastuzumab PET uptake was observed in patients whose tumors were considered by pathologic assessment to be HER2 negative.

![Figure 1](image1.png)

**Figure 1**: $^{64}$Cu-DOTA-trastuzumab uptake in HER2 negative patients. Arrows indicate $^{64}$Cu-positive lesions in (A) the left breast and right axilla of a patient with HER2 2+/FISH- disease, and (B) the right mastectomy bed of a patient with HER2 1+ disease.

2.) $^{64}$Cu-DOTA-trastuzumab PET uptake was directly related to the degree of HER2 positivity by IHC assessment. (Figure 2)
4. KEY RESEARCH ACCOMPLISHMENTS:
In this research grant we were able to demonstrate that:

a. $^{64}$Cu-DOTA trastuzumab PET/CT imaging is feasible.
b. The pre-administration of trastuzumab 50 mg resulted in a 75% decrease in hepatic uptake of $^{64}$Cu and resulted in improved image quality.
c. In women with metastatic HER2 positive breast cancer $^{64}$Cu-DOTA trastuzumab PET/CT imaging was comparable to FDG-PET/CT in the identification of metastatic disease.
d. In women with metastatic HER2 negative breast cancers, the uptake of $^{64}$Cu-DOTA trastuzumab on PET/CT was less intense than for women with HER2 positive disease.

5. CONCLUSION: We were able to demonstrate the feasibility of using $^{64}$Cu labeled trastuzumab for PET imaging. We were able to improve the quality of the PET images by pre-administering 45 mg of trastuzumab. Even HER2 negative breast cancers demonstrate uptake of $^{64}$Cu-DOTA-trastuzumab PET.

6. PUBLICATIONS, ABSTRACTS, AND PRESENTATIONS:

a. Our first manuscript entitled “” is In Press in the Journal of Nuclear Medicine and will be published in the January 2014 issue. The second manuscript is in preparation.

b. The data were presented at the following meetings as poster presentations:
   a. ASCO May 2012 and 2013
   b. San Antonio Breast Cancer Symposium 2012 and 2013
   d. Radiologic Society of North America 2012

c. Data were presented at two institutional Cancer Center Retreats for the Phase I Research meeting 2013.

7. INVENTIONS, PATENTS AND LICENSES: NA

8. REPORTABLE OUTCOMES:
Other investigators have tested the use of either Indium-111 or Copper-64 labeled trastuzumab. Prior clinical studies have generally included patients who were already on treatment with trastuzumab and the determination of HER2 status was based on the status of the primary cancer. Participants in our trial underwent biopsy of a metastatic focus prior to imaging and patients could not have received a HER2-directed therapy for more than 60 days. Therefore, we have knowledge of the HER2 status immediately prior to imaging and the co-administration of therapeutic trastuzumab did not confound our results. We were able to demonstrate that a small dose of pre-administered trastuzumab improved the image quality. We also demonstrated that the uptake of $^{64}$Cu-DOTA-trastuzumab on PET imaging correlated with the intensity of HER2 staining by immunohistochemistry. $^{64}$Cu-DOTA-trastuzumab PET uptake was observed in women whose cancers were considered HER2 negative by current pathologic criteria. Given this interesting observation, we hypothesize that $^{64}$Cu-DOTA-trastuzumab PET uptake may help to identify women who might benefit from the therapeutic immunoconjugate, T-DM1, including women with HER2 negative breast cancers.
9. OTHER ACHIEVEMENTS: Nothing to report.

Women with human epidermal growth factor receptor 2 (HER2)-positive breast cancer are candidates for treatment with the anti-HER2 antibody trastuzumab. Assessment of HER2 status in recurrent disease is usually made by core needle biopsy of a single lesion, which may not represent the larger tumor mass or other sites of disease. Our long-range goal is to develop PET of radiolabeled trastuzumab for systemically assessing tumor HER2 expression and identifying appropriate use of anti-HER2 therapies. The purpose of this study was to evaluate PET/CT of $^{64}$Cu-DOTA-trastuzumab for detecting and measuring tumor uptake of trastuzumab in patients with HER2-positive metastatic breast cancer. Methods: Eight women with biopsy-confirmed HER2-positive metastatic breast cancer and no anti-HER2 therapy for 4 mo or longer underwent complete staging, including $^{18}$F-FDG/PET/CT. For 6 of the 8 patients, $^{64}$Cu-DOTA-trastuzumab injection (364–512 MBq, 5 mg of trastuzumab) was preceded by trastuzumab infusion (45 mg). PET/CT (PET scan duration 1 h) was performed 21–25 (day 1) and 47–49 (day 2) h after $^{64}$Cu-DOTA-trastuzumab injection. Scan fields of view were chosen on the basis of $^{18}$F-FDG/PET/CT. Tumor detection sensitivity and uptake analysis were limited to lesions identifiable on CT; lesions visualized relative to adjacent tissue on PET were considered PET-positive. Radiolabel uptake in prominent lesions was measured as maximum single-voxel standardized uptake value (SUV$_{max}$). Results: Liver uptake of $^{64}$Cu was reduced approximately 75% with the 45-mg trastuzumab pretreatment, without significant effect on tumor uptake. The study included 89 CT-positive lesions; detection sensitivity was 77%, 89%, and 93% for day 1, day 2, and $^{18}$F-FDG, respectively. On average, tumor uptake was similar for $^{64}$Cu-DOTA-trastuzumab and $^{18}$F-FDG (mean SUV$_{max}$ and range were 8.1 and 3.0–22.5, respectively, for day 1 [$n$ = 48]; 8.9 and 0.9–28.9, respectively, for day 2 [$n$ = 38]; and 9.7 and 3.3–25.4, respectively, for $^{18}$F-FDG [$n$ = 56]), but same-lesion SUV$_{max}$ was not correlated between the 2 radiotracers. No toxicities were observed, and estimated radiation dose from $^{64}$Cu-DOTA-trastuzumab was similar to $^{18}$F-FDG. Conclusion: $^{64}$Cu-DOTA-trastuzumab visualizes HER2-positive metastatic breast cancer with high sensitivity and is effective in surveying disseminated disease. A 45-mg trastuzumab predose provides a $^{64}$Cu-DOTA-trastuzumab biodistribution favorable for tumor imaging. $^{64}$Cu-DOTA-trastuzumab PET/CT warrants further evaluation for assessing tumor HER2 expression and individualizing treatments that include trastuzumab.

Key Words: $^{64}$Cu-labeled trastuzumab; HER2; breast cancer

Overexpression of human epidermal growth factor receptor 2 (HER2) is identified in 20% of breast cancers (1). Women with HER2-positive breast cancer are candidates for treatment with the humanized anti-HER2 antibody trastuzumab. When combined with chemotherapy, trastuzumab increases overall survival for all stages of HER2-positive breast cancer.

Trastuzumab is used in newly diagnosed HER2-positive breast cancer as adjuvant or neoadjuvant therapy and as treatment for metastatic disease at presentation or relapse if more than 6 mo since adjuvant trastuzumab. Response rates are at best about 25% and 50%, respectively, for first-line trastuzumab and trastuzumab plus chemotherapy (2). Furthermore, in the adjuvant setting, patients classified as HER2-negative sometimes benefit (3). There is a clear need to better identify those patients who may benefit from these costly and potentially toxic therapies.

The accurate and comprehensive assessment of tumor HER2 status is critical in determining treatment. However, the pathologic assessment of HER2 status suffers from interlaboratory discordance and lack of a clear definition of positivity (4). Furthermore, confirmation of recurrent disease is usually made by core needle biopsy of an accessible lesion and may not represent the larger tumor mass or other sites of disease. Differences in HER2 expression between primary and metastatic tumors have been observed in as many as 20% of patients, especially when metastasis occurs after adjuvant or neoadjuvant therapy (5–7).

We hypothesized that assessment of tumor HER2 status can be improved by supplementing pathologic evaluation with functional imaging of HER2. Radiolabeled trastuzumab has been used to image patients with HER2-positive breast cancer, initially with $^{111}$In and single-photon imaging (8,9) and more recently with $^{89}$Zr and PET (10). Although labeling with the positron-emitting isotope $^{111}$In is also a possibility, radiometals are preferred given the known cellular internalization of trastuzumab and subsequent rapid efflux of radiolabel from cells when trastuzumab is labeled with $^{64}$Cu.
isotopes of iodine (11). Tumor visualization has been variable, perhaps because the women were on active trastuzumab treatment, which may have inhibited radiolabeled trastuzumab binding to HER2.

The positron-emitting isotope $^{64}$Cu is regularly available from Washington University, St. Louis, and we have extensive experience labeling antibodies with radiometals via the chelating agent DOTA (12). Although its half-life (12.8 h) is short relative to the blood clearance of trastuzumab, $^{64}$Cu has potential advantages over $^{89}$Zr in terms of radiation safety and patient radiation dose. The critical issue, addressed in this study, is whether tumor uptake of $^{64}$Cu-DOTA-trastuzumab is sufficiently rapid to support tumor imaging and quantification within the 48-h time window afforded by $^{64}$Cu. On the basis of our previous clinical study with $^{111}$In-MxDTPA-trastuzumab (9) and promising results in athymic mice bearing HER2-expressing human breast adenocarcinoma xenografts (13), we have obtained an investigational new drug (IND) application for $^{64}$Cu-DOTA-trastuzumab.

The primary objective of this pilot study was to evaluate the feasibility and potential utility of CT-supplemented PET scanning of $^{64}$Cu-DOTA-trastuzumab ($^{64}$Cu-DOTA-trastuzumab PET/CT) for lesion detection and uptake measurement in HER2-positive metastatic breast cancer. Similar to other antibodies (14), liver uptake of intravenously administered trastuzumab is strongly dependent on antibody protein load. Thus, we sought to identify a trastuzumab dose that minimizes liver uptake of $^{64}$Cu-DOTA-trastuzumab. Additional goals were to compare $^{64}$Cu-DOTA-trastuzumab with the standard PET radiotracer, $^{18}$F-FDG, and to confirm the safety of the $^{64}$Cu-DOTA-trastuzumab PET/CT procedure.

MATERIALS AND METHODS

Patient Selection

Women with metastatic HER2-positive breast cancer who had not received HER2-directed therapy for 4 mo or more were considered for study participation after undergoing a staging workup that included echocardiogram, bone scanning, and whole-body $^{18}$F-FDG/PET/CT. All candidates underwent biopsy of a metastatic lesion within 28 d before the $^{64}$Cu-DOTA-trastuzumab procedure to confirm recurrent, HER2-positive disease by immunohistochemical staining or fluorescence in situ hybridization. Assessable disease outside the primary breast site, ipsilateral axillary region, and biopsy site was also required. The study protocol was approved by the City of Hope Institutional Review Board and Radiation Safety Committee, and an IND was accepted by the Food and Drug Administration. All patients signed a written informed consent.

$^{64}$Cu-DOTA-Trastuzumab Preparation

Trastuzumab is a recombinant humanized antibody that binds with high affinity to the extracellular domain of the HER2 protein. Radiolabeled trastuzumab was prepared according to procedures defined in IND #109971. The antibody (Herceptin, purchased from Genentech) was conjugated with the active ester of DOTA (Macrocyclics) under current good manufacturing–compliant conditions. $^{64}$Cu (half-life, 12.8 h; 0.18 positrons/decay) was provided by the Mallinckrodt Institute of Radiology, Washington University School of Medicine. DOTA-conjugated antibody was incubated with $^{64}$Cu for 45 min at 43°C, chased with 1 mM diethylenetriamine pentaacetic acid (DTPA), and purified on a size-exclusion, preparative column (Superdex-200). Radiolabeling efficiency was more than 93%. Appropriate fractions were pooled, filtered, and formulated with 1% human serum albumin for patient administration. The $^{64}$Cu-DOTA-trastuzumab preparations were sterile, with endotoxin levels less than 0.05 EU/mL, and immunoreactivity greater than 86%. The DOTA-trastuzumab protein dose per $^{64}$Cu-DOTA-trastuzumab injection was approximately 5 mg.

Administration of Trastuzumab and $^{64}$Cu-DOTA-Trastuzumab

Patients were closely monitored for acute adverse reactions during trastuzumab administrations. $^{64}$Cu-DOTA-trastuzumab (364–512 MBq; mean, 450 MBq) was infused intravenously in 25 mL of saline over 10 min. Dijkers et al. found that, compared with 10 mg, 50 mg of trastuzumab substantially reduced blood clearance and liver uptake of $^{89}$Zr-trastuzumab in trastuzumab-naïve patients (10). To match the trastuzumab dose found effective in that study, patients receiving nonradiolabeled trastuzumab were infused intravenously with the antibody (45 mg in 50 mL of saline given over 15 min) immediately before radioactive injection.

The first 4 patients in our study were randomly assigned to receive trastuzumab doses of 5 or 50 mg. When $^{64}$Cu-DOTA-trastuzumab PET/CT of those patients confirmed the findings of Dijkers et al., we adopted the 50-mg dose for the remainder of the study.

PET/CT Imaging

Imaging was performed with a Discovery StE 16 PET/CT scanner (GE Healthcare) operated in 3-dimensional mode (septa retracted). The PET axial field of view is 15.4 cm (image slice thickness, 3.3 mm). PET images were reconstructed using an iterative, ordered-subsets expectation maximization algorithm with gaussian postsmoothing and standard corrections for nonuniform detector sensitivity, scanner dead time, random, and scattered coincidence events. Correction for photon attenuation was based on coregistered CT scans acquired during the same examination. The measured spatial resolution of the PET images was approximately 9 mm in full width at half maximum.

Patients underwent a standard $^{18}$F-FDG/PET/CT examination 13 d or fewer before the $^{64}$Cu-DOTA-trastuzumab procedure. Patients fasted 6 h or more before injection of $^{18}$F-FDG. Serum glucose concentration measured at time of examination was high (184 mg/dL) for one patient and normal (<120 mg/dL) for the others.

Injected $^{64}$Cu activity was limited to 555 MBq (15 mCi), based on radiation dose estimates calculated from the pharmacokinetics of $^{111}$In-MxDTPA-trastuzumab (9). One hour was chosen as a reasonable limit for PET scan duration. Within those constraints, disease location as judged from the preceding $^{18}$F-FDG PET/CT examination was used in choosing the axial coverage for the $^{64}$Cu-DOTA-trastuzumab PET/CT scans. The first (day 1) $^{64}$Cu scan was performed 21–25 h after injection to allow radiolabeled antibody accumulation in tumor. A second (day 2) scan was obtained 47–49 h after injection. Day 1 scans comprised of 3 or 4 (39 or 51 cm axial extent, 20 or 15 min per bed position) and day 2 scans comprised of 1 or 2 (15 or 27 cm axial extent, 60 or 30 min per bed position) contiguous bed positions, respectively, depending on patient body thickness. Signal-to-noise characteristics of the $^{64}$Cu-DOTA-trastuzumab images approximated those of the $^{18}$F-FDG scans (Fig. 1).

Image Analysis

PET/CT examinations were interpreted by a nuclear medicine boarded radiologist. Tumor detection sensitivity and uptake analysis were limited to lesions identifiable on CT; lesions visualized relative to adjacent tissue on PET were considered PET-positive. PET-positive lesions were disregarded if CT was judged inconclusive. PET-positive findings with $^{64}$Cu-DOTA-trastuzumab but not $^{18}$F-FDG, and having no correlated CT lesion, were scored as false-positives. Because of possible $^{18}$F-FDG or nonspecific antibody uptake secondary to biopsy, biopsied tumor sites were not included in the analysis. A detailed description of the lesion detection analysis is given in the supplemental material (available only online at http://jnm.snmjournals.org).

Radiolabel uptake in as many as 10 of the most prominent lesions per patient, as well as selected nontumor tissues and organs, was measured in terms of standardized uptake value (SUV = tissue activity
Uptake analysis for blood, liver, spleen, kidney, and heart wall consisted of averaging the mean SUVs of circular or elliptic regions of interest of fixed size placed well within the tissue’s or organ’s PET image boundaries on 3 contiguous image slices. Blood measurements were obtained from PET images of the cardiac ventricles; heart wall was visualized as a region of relatively low uptake adjacent to the ventricles.

Pharmacokinetic Analysis and Radiation Dose Estimates

$^{64}$Cu activity concentration was measured in peripheral venous samples acquired 0–1, 23–24, and 47–48 h after injection from patients who received a 50-mg trastuzumab dose. Radiation dose estimates for these patients were obtained by combining blood activity and organ uptake measurements from the current study with blood and organ time–activity measurements (0–168 h) from our previous clinical study with $^{111}$In-MxDTPA-trastuzumab (9). Details of the radiation dose calculations are given in the supplemental material.

Human Anti-Trastuzumab Antibody Response

Serum samples obtained just before trastuzumab/$^{64}$Cu-DOTA-trastuzumab infusion and 1, 3, and 6 mo later, when possible, were evaluated for immune responses using a size-exclusion high-performance liquid chromatography shift assay. Samples (125 μL) were incubated with radiolabeled DOTA-trastuzumab ($^{111}$In, 9 μCi/μg, 0.1 μCi) and then run on a Superox-6 size-exclusion column at 0.4 mL/min in phosphate-buffered saline/0.05% NaN₃. A change in the elution pattern of the radiolabeled trastuzumab consistent with higher molecular weight was considered positive for an antiantibody response.

Statistical Analysis

Statistical analysis was performed using R software (version 2.12.1, [AQ9] The R Foundation of Statistical Computing). Lesion detection sensitivities were compared by a 2-sided Fisher exact test. Comparison of tumor uptake between trastuzumab doses and among lesion sites used ANOVA to evaluate both dose/lesion site and patient effects, with Holm’s method to adjust for multiple comparisons. Linear regression analysis was used to demonstrate correlation between whole-tumor SUV and SUV max and lack of correlation between $^{18}$F-FDG and $^{64}$Cu-DOTA-trastuzumab. The effect of trastuzumab dose on organ uptake was evaluated by Wilcoxon rank-sum test. $P$ values of less than 0.05 were considered statistically significant.

RESULTS

Patient Characteristics

Eight of 10 women considered for study participation met the eligibility criteria. Biopsies of 2 patients previously treated for early stage HER2-positive breast cancer showed recurrent disease to be HER2-negative. Participating patients are characterized in Table 1. [Table 1]

Lesion Detection Sensitivity of $^{64}$Cu-DOTA-Trastuzumab PET/CT

Figure 1 illustrates $^{64}$Cu-DOTA-trastuzumab image quality and tumor visualization, compared with $^{18}$F-FDG. Tumor-to-nontumor contrast for $^{64}$Cu-DOTA-trastuzumab was generally high (Fig. 1, A).

TABLE 1

Patient Demographics and Clinical Characteristics

$^{64}$Cu-TRASTUZUMAB PET IN HER2+ BREAST CANCER • Mortimer et al.
Lesion detection statistics are summarized in Table 2. Overall detection sensitivity with \(^{18}\text{F}-\text{FDG}\) PET/CT (93%) was consistent with general experience in metastatic breast cancer (16). All 8 patients had CT-positive lesions that were detected with \(^{64}\text{Cu}-\text{DOTA}\)-trastuzumab PET. There were no statistically significant differences in \(^{64}\text{Cu}\) lesion detection sensitivity between 5- and 50-mg trastuzumab doses (data not shown). On day 1, \(^{64}\text{Cu}\) detection sensitivity was lower for lymph nodes than for bone lesions. Overall, detection sensitivity for \(^{64}\text{Cu}-\text{DOTA}\)-trastuzumab on day 1 was lower than for \(^{18}\text{F}-\text{FDG}\), with the difference being due primarily to the low sensitivity of lymph nodes in regions of high blood activity. There were 7 instances in which a CT-positive lesion was detected with \(^{18}\text{F}-\text{FDG}\) but not \(^{64}\text{Cu}-\text{DOTA}\)-trastuzumab on either day 1 or day 2. In 6 instances (3 bone, 2 liver, and 1 node), a CT-positive lesion was detected with \(^{64}\text{Cu}-\text{DOTA}\)-trastuzumab but not with \(^{18}\text{F}-\text{FDG}\). \(^{18}\text{F}\) FDG false-negative bone and liver lesions are illustrated in Figures 2 and 3B, respectively.

There was only 1 instance of a false-positive \(^{64}\text{Cu}-\text{DOTA}\)-trastuzumab lesion, which occurred in the colon and may have been associated with diverticulitis. In 1 patient with numerous bone metastases, \(^{64}\text{Cu}-\text{DOTA}\)-trastuzumab, or both \(^{64}\text{Cu}-\text{DOTA}\)-trastuzumab and \(^{18}\text{F}\)-FDG, produced hot spots in rib regions too small to be assessed on associated CT (Fig. 1, patient A).

**Effects of Trastuzumab Protein Dose**

Blood clearance was slowed, and liver uptake of \(^{64}\text{Cu}-\text{DOTA}\)-trastuzumab was markedly decreased in patients preinfused with trastuzumab (45 mg) (supplemental material, Fig. 1). However, with only 2 patients at the lower protein dose, SUV differences between the 50- and 5-mg trastuzumab doses were not statistically significant (\(P = 0.10\) and 0.05 on days 1 and 2 for blood; \(P = 0.10\) and 0.07 on days 1 and 2 for liver). Trastuzumab predosing dramatically improved visualization of hepatic metastases (Fig. 3) and had little effect on \(^{64}\text{Cu}-\text{DOTA}\)-trastuzumab uptake in heart wall (supplemental material, Fig. 1), kidney, or spleen (data not shown).

No statistically significant difference in tumor uptake of \(^{64}\text{Cu}-\text{DOTA}\)-trastuzumab was observed between the 2 trastuzumab doses. Tumor SUV\(_{\text{max}}\) was generally higher for the 5- than for the 50-mg dose on day 1 (mean \(\pm\) SD, 11.3 \(\pm\) 5.9, compared with 6.7 \(\pm\) 2.4, \(P = 0.01\)) but trended in the other direction on day 2 (mean \(\pm\) SD, 5.9 \(\pm\) 3.7, compared with 9.6 \(\pm\) 5.9, \(P = 0.11\)). When ANOVA included both a patient effect (i.e., accounted for varying numbers of lesions among different patients) and a dose effect, there was no significant trastuzumab dose effect on either day.

**Heterogeneity of \(^{64}\text{Cu}-\text{DOTA}\)-Trastuzumab Uptake in Tumors**

Uptake varied widely both among and within patients (Fig. 4). For the data included in Figure 4, mean SUV\(_{\text{max}}\) ranged from 5.5 to 15.0 g/mL among the 8 patients. Within patients, SUV\(_{\text{max}}\) varied between 2- and 5-fold in 7 patients and 22-fold in 1 patient.

**Tumor Uptake Compared Between \(^{64}\text{Cu}-\text{DOTA}\)-Trastuzumab and \(^{18}\text{F}-\text{FDG}\)**

Uptake of \(^{64}\text{Cu}-\text{DOTA}\)-trastuzumab and \(^{18}\text{F}\)-FDG was comparable when averaged over all lesions. For combined 5- and 50-mg trastuzumab doses, SUV\(_{\text{max}}\) mean, median, and range results were 9.7, 9.3, and 3.3–25.4, respectively, for \(^{18}\text{F}-\text{FDG}\) (\(n = 56\)); 8.1, 7.0, and 3.0–22.5, respectively, for \(^{64}\text{Cu}-\text{DOTA}\)-trastuzumab day 1 (\(n = 48\)); and 9.0, 7.5, and 0.9–28.9, respectively, for \(^{64}\text{Cu}-\text{DOTA}\)-trastuzumab day 2 (\(n = 38\)).

ANOVA including both lesion site and patient effects indicated significant lesion site effects for both \(^{64}\text{Cu}-\text{DOTA}\)-trastuzumab and \(^{18}\text{F}-\text{FDG}\) (Fig. 5). Pairwise comparisons between sites showed \(^{18}\text{F}-\text{FDG}\) uptake in liver metastases to be less than in bone metastases (\(P < 0.01\)), whereas \(^{64}\text{Cu}-\text{DOTA}\)-trastuzumab uptake on day 2 was higher in liver metastases than in bone metastases (\(P < 0.02\)).

Same-lesion SUV\(_{\text{max}}\) for \(^{64}\text{Cu}-\text{DOTA}\)-trastuzumab and \(^{18}\text{F}-\text{FDG}\) was uncorrelated (\(P \cong 0.4\); correlation coefficients = –0.1). SUV\(_{\text{max}}\) ratios (\(^{64}\text{Cu}-\text{DOTA}\)-trastuzumab to \(^{18}\text{F}\)-fdg) varied from 0.2 to 4.3 (supplemental material, Fig. 2).

**Patient Safety**

Trastuzumab infusion and \(^{64}\text{Cu}-\text{DOTA}\)-trastuzumab PET/CT were well tolerated, with no unanticipated toxicity or adverse side effects observed. Antitratustumab antibody response assays were negative for 6 patients. Minor increases in higher-molecular-weight
complexes were observed in the high-performance liquid chromatography shift assays of 2 patients at baseline and 6 mo or baseline, 3, and 6 mo after their 64Cu-DOTA-trastuzumab PET/CT procedures. Estimated radiation doses (Table 3) were well within the range of those for established radionuclide imaging procedures.

**DISCUSSION**

Tumor HER2 status and trastuzumab exposure history were more clearly prescribed in the current investigation than in prior imaging studies with trastuzumab (8–10). All patients had biopsy confirmation of HER2 positivity at time of study, and none had received anti-HER2 therapy for at least 4 mo before imaging.

We have clearly shown that, despite the relatively short half-life of the radiolabel, 64Cu-DOTA-trastuzumab PET/CT can effectively detect and quantify tumor uptake in patients with known HER2-positive disease. Other than brain, all anatomic sites common to metastatic breast cancer were included in the patient cohort. Lesions were visualized in all 8 patients examined and were seen in bone, lymph nodes, liver, lung, pleural effusions, and breast. Detection sensitivity was 77% on day 1 and 89% on day 2 (Table 2). Tumor uptake was substantial by 24 h and, on average, increased modestly between 24 and 48 h. Detection of lymph nodes in the neck, upper thorax, and mediastinum is difficult at 24 h because of high blood background but improves by 48 h (Fig. 2). The chief limitation of 64Cu-DOTA-trastuzumab PET/CT is that, because of the 13-h half-life of 64Cu, it does not provide whole-body coverage with acceptable signal-to-noise ratio and scan duration. Nonetheless, as demonstrated here, 64Cu-DOTA-trastuzumab PET can be used effectively in disseminated, HER2-positive breast cancer when disease location is defined in advance by 18F-FDG/PET or CT.

A second major objective was to establish a trastuzumab protein load that minimizes liver uptake without inhibiting tumor uptake of 64Cu-DOTA-trastuzumab. We observed that adding 45 mg of trastuzumab to the 5 mg of DOTA-trastuzumab delivered with the radioactive injection approximately doubled blood SUV and reduced liver uptake by 75%–80% on days 1 and 2 after radiotracer injection (supplemental material, Fig. 1). These observations are quantitatively similar to those reported by Dijkers et al. for 89Zr-trastuzumab given with trastuzumab loads of 10 and 50 mg (10).

Comparison with our 111In-MxDTPA-trastuzumab study (4 lesions visualized in 3 of 7 patients with known lesions) dose would not yield further improvement in the pharmacokinetics or biodistribution of 64Cu-DOTA-trastuzumab. We observed no statistically significant difference in tumor uptake between 5- and 50-mg doses in this small study. However, other investigations have demonstrated that a significant fraction of tumor binding sites can be occupied at antibody loading doses << 4–8 mg/kg (17). Furthermore, the dissociation constant for 111In-DTPA-trastuzumab-HER2 binding is approximately 10 nM (18), a concentration that very likely would be exceeded in tumors at a trastuzumab load of 4–8 mg/kg. This suggests that HER2 saturation may have contributed to the relatively low tumor detection sensitivity in our 111In-MxDTPA-trastuzumab study (4 lesions visualized in 3 of 7 patients with known lesions).

![RGB](image)

**FIGURE 3.** Visualization of hepatic metastases. (A) Fused transaxial PET/CT images of 18F-FDG and 64Cu-DOTA-trastuzumab 21 h after injection for patient (patient A) given 5 mg of trastuzumab. Upper intensity thresholds (white color) correspond to SUV = 10 g/mL for 18F-FDG and 40 g/mL for 64Cu-DOTA-trastuzumab. (B) Fused transaxial PET/CT images of 18F-FDG and 64Cu-DOTA-trastuzumab 47 h after injection for patient (patient B) given 50 mg of trastuzumab. Upper intensity thresholds correspond to SUV = 10 g/mL. Arrows indicate detected lesions. For patient A, anterior hepatic lesion is visualized as cold spot on 64Cu-DOTA-trastuzumab scan. Liver SUV was 27.6 g/mL in patient A, compared with 5.5 g/mL in patient B, for whom hepatic lesions are dramatically visualized as hot spots. For patient B, 2 lesions not seen with 18F-FDG are detected with 64Cu-DOTA-trastuzumab.
Heterogeneity of tumor HER2 expression within and among patients is poorly understood (5–7) and may be elucidated by imaging studies with radiolabeled trastuzumab. The high degree of tumor positivity observed in the current study suggests that most lesions in HER2-positive patients have HER2 expression adequate to render them detectable with 64Cu-DOTA-trastuzumab PET/CT. On the other hand, tumor uptake was also highly variable among and within patients (Fig. 4). That heterogeneity suggests a potential role for 64Cu-DOTA-trastuzumab PET/CT in the selection of patients for trastuzumab-based therapy.

Patient selection and scan design for the 64Cu-DOTA-trastuzumab PET examinations relied on prior 18F-FDG scans. Tumor uptake and detection sensitivity were only modestly lower for 64Cu-DOTA-trastuzumab than for 18F-FDG. Most lesions were positively visualized with both radiotracers, and 6 CT-positive tumors were detected with 64Cu-DOTA-trastuzumab and not with 18F-FDG. Same-lesion maximum SUVs for 64Cu-DOTA-trastuzumab and 18F-FDG were uncorrelated, and their ratios (64Cu-DOTA-trastuzumab to 18F-FDG) varied by a factor of 22 (supplemental material, Fig. 2).

Tumor uptake of 18F-FDG reflects density of glycolytic activity, which in turn depends on viable cell density and tissue oxygenation status (19–21). In breast cancer, high tumor uptake of 18F-FDG is generally correlated with tumor aggressiveness but not with overexpression of the HER2 oncogene c-erbB-2 (22). For 64Cu-DOTA-trastuzumab, the unproven assumption is that tumor uptake is closely related to HER2 density, which in turn is positively correlated with tumor growth rate and aggressiveness (23). However, the relationship between uptake and HER2 expression may be confounded by factors such as blood clearance and vascular permeability. Because glycolysis and HER2 expression are independently related to tumor aggressiveness, the observed lack of correlation between same-tumor uptake of 64Cu-DOTA-trastuzumab and 18F-FDG suggests that combining the 2 measurements may be useful in predicting patient outcomes.

The procedures used in this study were well tolerated. There were no unexpected toxicities associated with the trastuzumab or 64Cu-DOTA-trastuzumab administrations. Two patients had assay results that might indicate low-level antiantibody responses after the 64Cu-DOTA-trastuzumab procedure. However, both patients had positive pre-Cu-DOTA-trastuzumab baseline assays and intermittingly positive assays thereafter. This suggests positivity resulted from something other than the 64Cu-DOTA-trastuzumab procedure, such as prior treatment with trastuzumab or the presence of circulating antigen (i.e., HER2 extracellular domain) in the serum, a possibility that we are currently evaluating.

Estimated radiation doses for 64Cu-DOTA-trastuzumab (Table 3) are moderate, compared with 18F-FDG and other imaging procedures with radiolabeled antibodies. For the mean administered activity in this study (450 MBq) and a 50-mg trastuzumab dose, estimated effective dose and maximum organ (heart wall) equivalent dose for 64Cu-DOTA-trastuzumab are 12 and 71 mSv, respectively. 18F-FDG has effective and critical organ (bladder wall) equivalent doses of 11 and 72 mSv, respectively, for the typical
injected activity of 555 MBq (15 mCi) (24). Monoclonal antibodies labeled with $^{111}$In incur effective and critical organ (spleen and liver) equivalent doses of approximately 40 and 200 mSv, respectively, for the typical injected activity of 185 MBq (5 mCi) (24). Dijkers et al. estimated a radiation dose (presumably effective dose) of 18 mSv from a 37-MBq (1 mCi) injection of $^{89}$Zr-trastuzumab (10).

CONCLUSION

We have shown that, in patients with HER2-positive metastatic breast cancer, tumors rapidly accumulate $^{64}$Cu-DOTA-trastuzumab to high concentrations, thus supporting both detection and measurement of tumor uptake by 1 d after injection. The rapid uptake, supplemented by prior knowledge of tumor location and extent, is supported by $^{18}$F-FDG PET/CT, makes $^{64}$Cu-DOTA-trastuzumab effective for surveying disseminated disease despite the limited half-life of $^{64}$Cu. We have confirmed that 50 mg of trastuzumab protein dose provides a $^{64}$Cu-DOTA-trastuzumab biodistribution favorable for tumor imaging. This study demonstrates that $^{64}$Cu-DOTA-trastuzumab PET/CT is a practical and acceptable safe procedure in patients with metastatic breast cancer.

We will next broaden the study to include patients with metastatic breast cancer classified as HER2-negative on prescan biopsy and thus correlate tumor uptake of $^{64}$Cu-DOTA-trastuzumab with HER2 expression. Beyond that, we envision using $^{64}$Cu-DOTA-trastuzumab PET/CT to individualize treatment regimens that include trastuzumab and other HER2 directed therapies.

San Antonio Breast Cancer Symposium 2013

Relationship between $^{64}\text{Cu}$-DOTA-trastuzumab positron emission tomography uptake and assessment of HER2 by immunohistochemistry in women with advanced breast cancer. Joanne E. Mortimer, David Colcher, Paul Frankel, Andrew Raubitschek, Mary Carroll, Peter Conti, Shan Tong, Kofi Poku, Joshua Miles, and James Bading.

**Background:** We have utilized $^{64}\text{Cu}$-DOTA-trastuzumab with PET imaging to assess the in vivo expression of HER2 in women with advanced breast cancer. We have demonstrated that a preadministered dose of trastuzumab 45 mg prior to injection of $^{64}\text{Cu}$-DOTA-trastuzumab resulted in a 75% decrease in the hepatic uptake of Cu-64, resulting in improved image quality.

**Methods:** Patients with biopsy confirmation of recurrent disease located outside the breast and axilla considered for study. Complete staging workup included CT of the chest, abdomen, and pelvis, bone scintigraphy and $^{18}\text{F}$ FDG PET. At least 1 non-hepatic site of metastasis that was > 2 cm separate from the biopsy site was also required. HER2 status was assessed by both IHC and FISH. Index lesions were identified on CT imaging. After the first two patients, all patients received a cold dose of 45mg of trastuzumab immediately prior to $^{64}\text{Cu}$-DOTA-trastuzumab to decrease liver uptake. $^{64}\text{Cu}$-DOTA-trastuzumab PET imaging was performed at 24 and 48 hours. Uptake on $^{64}\text{Cu}$-DOTA-trastuzumab was correlated with HER2 status by IHC and FISH.

**Results:** Fifteen women have undergone $^{64}\text{Cu}$-DOTA-trastuzumab PET imaging and quantitative image analysis. 10 patients were HER2+ (7 IHC 3+, 3 IHC 2+/FISH+), 3 patients were IHC 2+/FISH-, and 2 patients were IHC 1+. Tumor uptake by $^{64}\text{Cu}$-DOTA-trastuzumab PET max SUV was higher in HER2+ positive than HER2- patients (1.9-fold higher on day1, p<0.02, and 1.7-fold higher on day2, p<0.05). However, the lowest max SUV was in a HER2+ patient (HER2 2+/FISH+), demonstrating considerable heterogeneity. Conclusion: $^{64}\text{Cu}$-DOTA-trastuzumab PET correlates with HER2+ status. However, due to high within and between patient variability, $^{64}\text{Cu}$-DOTA-trastuzumab PET imaging could potentially enrich for HER2+ patients that respond to HER2-targeted therapy, and could also suggest some HER2- patients that may benefit from HER2-targeted therapy. This hypothesis needs to be further explored in patients undergoing HER2-targeted therapy. This work was supported by the Department of Defense grant # BC095002.
64Cu-DOTA-trastuzumab positron emission tomography imaging of HER2 in women with advanced breast cancer

Joanne E Mortimer, Jinha Mark Park, Mary I. Carroll, Kofi Poku, Joshua Miles, David Colcher, Andrew A. Raubitschek, Peter Conti, Tri Tran, and James R. Bading

City of Hope Cancer Center/Beckman Research Institute, Duarte, CA; USC, Los Angeles, CA 91010

Abstract

Background: We have developed 64Cu-DOTA-trastuzumab for PET imaging of HER2-positive breast cancer. We have determined that administering trastuzumab (45 mg) prior to 64Cu-DOTA-trastuzumab sharply reduces the tumor uptake of the radiolabeled trastuzumab. We are now testing whether tumor uptake of 64Cu-DOTA-trastuzumab correlates with variable IHC staining in women with advanced breast cancer.

Methods: Eligibility criteria included biopsy confirmation of metastatic disease that was HER2 1+, 2+, or 3+ by IHC, no anti-HER therapy within the prior 4 weeks, and at least 1 non-hepatic site of metastases ≥2 mm outside the biopsy site. Staging workup included 64Cu-FDG PET-CT. Patients received 45 mg of cold trastuzumab prior to 64Cu-DOTA-trastuzumab. PET-CT scans were obtained at 21-25 h (Day 0) and 48-52 h (Day 1) after trastuzumab injection.

Results: Fourteen women (median age 56, range 35-75 years) have undergone imaging. HER2 status by IHC staining was 1+, 2+, or 3+ in 12 women. All women had HER2-positive breast cancer. All tumors were scanned with 64Cu-DOTA-trastuzumab, and lesions were measured in terms of maximum single-voxel SUV (SUVmax). Lesions identified on CT and judged to have image intensity > adjacent tissue by an expert radiologist were considered positive on PET.

Conclusions: 64Cu-DOTA-trastuzumab PET imaging is feasible and may predict for drug resistance. Tumor uptake of 64Cu-DOTA-trastuzumab-PET in IHC 1+ and 2+ patients was lower in HER2 patients (SUVmax mean ± SEM: Day 1 8.9 ± 0.2 vs Day 2 9.9 ± 0.8; p < 0.001) compared with HER2- patients (SUVmax mean ± SEM: Day 1 7.2 ± 0.6 vs Day 2 7.9 ± 0.6; p < 0.001). The pre-administration of 50 mg trastuzumab resulted in a 75% decrease in hepatic uptake, improving image quality.

Study 1 Summary of Results

1. 25-30% of all breast cancers overexpress the HER2 protein as assessed by IHC or FISH.
2. HER2 overexpression is used to guide the use of HER-directed therapy with trastuzumab.
3. Following systemic therapy, the HER2 status may change in 5-30% of patients and re-biopsy of recurrent tumor may be difficult.
4. Functional imaging with PET provides information about tumor biology and may predict for drug resistance.
5. Normal tissues express HER2 and may uptake radiolabeled trastuzumab compromising PET image quality.

Conclusions

In eight women with documented HER2 positive metastatic disease:

1. Pre-administration of 50 mg trastuzumab resulted in a 75% decrease in hepatic uptake, improving image quality.
2. The pre-administration of trastuzumab PET imaging is feasible.

Study 2 Summary

- In general uptake on 64Cu-DOTA-trastuzumab PET correlated with HER2 status determined by IHC.
- We continue to accrue patients to Study 2.

Results - Study 2

64Cu-DOTA-trastuzumab PET uptake and HER2 status by IHC staining 1+, 2+, 3+.

Inter- and intra-patient heterogeneity of 64Cu-DOTA-trastuzumab tumor uptake. Data are from DAY 1 (n = 90), (DAY 2 (n = 9) for lesions not included in the DAY 1 scan. Seven of the DAY 2 lesions are for Patient 14, for whom data from 2 of the 3 scanned bed positions on DAY 1 were lost due to scanner malfunction.

Functional imaging of HER2-positive metastatic breast cancer using 
\textsuperscript{64}Cu-DOTA-Trastuzumab Positron Emission Tomography (PET)

Joanne E. Mortimer, Peter Conti, Shan Tong, Jose Reyes, Mary I. Carroll, Kofi Poku, David Colcher, Andrew A. Raubitschek, James R. Bading, Joshua Miles,
\textsuperscript{1}Dept Medical Oncology and Experimental Therapeutics, \textsuperscript{2}Cancer Immunotherapeutics and Tumor Immunology City of Hope Cancer Center/Beckman Research Institute, Duarte, CA; USC, Los Angeles, CA 91010

\section*{Background}
- 25-30\% of all breast cancers overexpress the HER2 protein as assessed by IHC or FISH.
- HER2 overexpression is used to guide the use of anti-HER therapy with trastuzumab.
- Following systemic therapy, the HER2 status may change in 5-30\% of patients and re-biopsy of recurrent tumor may be difficult.
- Functional imaging with PET provides information about tumor biology and may predict for drug resistance.
- Normal tissues express HER2 and may uptake radiolabeled trastuzumab compromising PET image quality.

\section*{Hypothesis}
\textsuperscript{64}Cu-DOTA-Trastuzumab PET image quality can be improved by a pre-injection of cold trastuzumab.

\section*{Eligibility}
1. Histological confirmation of metastatic invasive breast cancer outside of the region of the primary tumor and axilla.
2. At least 1 non-hepatic site of metastasis > 2 cm in mean diameter in addition to the site that was biopsied.
3. The HER2 positive by IHC and/or FISH.
4. No prior anti-HER therapy within 2 months.
5. Normal cardiac ejection fraction.

\section*{Study Design}
- \textsuperscript{18}F-FDG whole body CT/PET
- Bone Scan
- Cardiac Ejection Fraction

\section*{Imaging}
\textbf{Day 0:} Injection of assigned cold dose (5 mg, 50 mg or 4mg/kg) trastuzumab
Injection of 15 mCi \textsuperscript{64}Cu-DOTA-Trastuzumab

\textbf{Day 1:} \textsuperscript{64}Cu-DOTA-Trastuzumab PET imaging
\textbf{Day 2:} \textsuperscript{64}Cu-DOTA-Trastuzumab PET imaging

\section*{Summary & Conclusions}
- \textsuperscript{64}Cu-DOTA-Trastuzumab PET imaging is feasible.
- The pre-administration of 50 mg Trastuzumab improves image quality.
- Myocardial uptake of \textsuperscript{64}Cu-DOTA-Tastuzumab was not appreciated.

Phase II of the study will enroll women with advanced breast cancer that is 1+, and 2+ HER2 positive.

This study was funded by a Department of Defense grant, BC095002.
64Cu-DOTA-TRASTUZUMAB (64Cu-HERCEPTIN)/PET EFFECTIVELY VISUALIZES METASTATIC BREAST CANCER IN HER2-POSITIVE PATIENTS

J. Bading1, D. Colcher1, P. Frankel1, S. Tong1, J. Reyes1, M. Carroll1, E. Poku1, J. Miles1, J. Wong1, J. Shively1, P. Conti2, A. Raubitschek1, J. Mortimer1, City of Hope, Duarte, CA; 2 University of Southern California, Los Angeles, CA

OBJECTIVES
1. Evaluate the feasibility and potential utility of 64Cu-DOTA-trastuzumab/PET-CT for detecting and quantifying HER2-positive metastatic breast cancer.
2. Investigate the effects of trastuzumab protein load on the pharmacokinetics, biodistribution and tumor uptake of 64Cu-DOTA-trastuzumab.
3. Compare imaging with PET-CT and 64Cu-DOTA-trastuzumab with 18F-FDG.
4. Evaluate 64Cu-DOTA-trastuzumab with regard to patient safety.

INTRODUCTION HER2
- Human epidermal growth receptor 2 (HER2)
- Observed in 25-30% of breast cancers
- Associated with metastasis and decreased survival

TRASTUZUMAB (HERCEPTIN®)
- Monoclonal antibody
- Binds to the extracellular domain of HER2
- Has significant anti-tumor effects
- Used in combination with chemotherapy for HER2-positive breast cancer

PREVIOUS IMAGING STUDIES WITH RADIOLabeled TRASTUZUMAB
- Radioisotopes are trapped in cells following antibody internalization and are therefore prefered over radioiodine as labeling agents for trastuzumab.
- We previously evaluated 89Zr-trastuzumab in combination with new, planar imaging and SPECT in 8 patients with advanced HER2+ breast cancer (Wong, et al., Cancer Biother & Radiopharm 2010;25:267-269).

RESULTS

PATIENTS
- 8 women, age 39-75
- Biopsy-proven HER2-positive metastatic disease ≤ 28 d prior to study
- HER2 expression levels on IHC: 2+ in 5 (or 1 + )
- 3+ in 3
- Normal cardiac function

METHODS

PET imaging
- GE Discovery ST/i 18F-FDG PET-CT
- Axial field of view 15.4 cm (47 slices)
- Operated in 3D mode
- Standard corrections for dead time, randoms, scatter, attenuation (CT-based)
- Scan placement and acquisition for 64Cu-DOTA-trastuzumab
- In done in reference to 18F-FDG/PET-CT
- Total acquisition time ≤ 15 h
- Day 1: 1 or 2 bed positions, 60 or 30 min ea
- Day 2: 1 or 2 bed positions, 60 or 30 min ea
- Bed-position overlap 30 cm
- Image reconstruction
- OSEM with Gaussian post-smoothing
- Image resolution: 9 mm FWHM

PET/CT IMAGING
- Trastuzumab dose
- 5 mg: n = 2 (concomitant with 60 mg 18F-FDG injection)
- 50 mg: n = 6 (45 mg infused prior to 64Cu-DOTA-trastuzumab injection)
- Biodistributions and blood clearance in the first 2 patients done at each dose level confirmed the findings of Dijkers, et al., with 64Cu-DOTA-trastuzumab.

PET/CT IMAGING
- Therefore we adopted the 50 mg dose going forward.
- PET imaging: 64Cu-DOTA-trastuzumab injected activity: mean 450 MBq range 364-512 MBq

IMAGE ANALYSIS
- Lesion detection
- Lesions judged to have intensity ≥ adjacent tissue were considered positive on PET.
- Biopsied tumor sites were included.
- Tumor uptake
- Measured for up to 10 prominent lesions/patient
- Metrics evaluated:
  - SUVmax, SUVmean, background-adaptive whole tumor average SUVw (SUVwmax)
  - Normalized to body weight (BW) & lean body mass (LBM)
- Metastatic lesion criteria:
  - Only SUVmax (BW) (Others were highly correlated with SUVwmax (BW) ≥ 5.91)

PHARMACOKINETIC ANALYSIS & RADIODETH Dose Estimates
- Blood sampling (i.v., 50 mg trastuzumab only): 1, 24 & 48 h after 64Cu-DOTA-trastuzumab injection
- Radiation dose calculations:
  - Blood & organ time-activity curves (1-168 h) from 111In-MxDTPA-trastuzumab study were scaled to 64Cu-DOTA-trastuzumab.
  - These adjusted residence times were input to the dosimetry program OLINDA.

HYPOTHESIS
- 64Cu ADVANTAGES & DISADVANTAGES
- Availability
- Routinely supplied by the Mallinckrodt Institute of Radiology, Washington University in St. Louis
- Physical characteristics
  - 64Cu: 63.3 min
  - 64Cu: 18.8% 63Cu at equilibrium
- 64Cu: 15.4 cm (47 slices)
- Life-time is 12.7 h short compared to 68GaDOTA-trastuzumab blood clearance.

SUMMARY/CONCLUSIONS
1. Although the half-life of 64Cu is less than ideal, 64Cu-DOTA-trastuzumab/PET-CT effectively visualized and provided uptake measurements for presumably HER2-positive metastatic lesions in bone, liver, lung, and, to a lesser degree, lymph nodes.
2. 50 mg trastuzumab protein dose reduced liver uptake of 64Cu by approximately 15% relative to 5 mg dose, permitting positive visual imaging of intranodal lymph nodes.
3. Uptake of 64Cu-DOTA-trastuzumab and 64Cu-FDG was uncorrelated within a given lesion, but comparable in magnitude when averaged over all lesions. Liver metastases observed in this study had higher 64Cu-DOTA-trastuzumab uptake relative to 64Cu-FDG than bone, nodal or lung metastases.
4. Administration of trastuzumab and 64Cu-DOTA-trastuzumab was not associated with any adverse events and no more low-level anti-trastuzumab antibody responses. Estimated radiation doses from 64Cu-DOTA-trastuzumab were moderate compared with those incurred by radiopharmaceuticals routinely used in medicine.

NEXT STEP: Add patients with a wide range of HER2 expression pre-scan biopsy to correlate HER2 expression with tumor uptake of 64Cu-DOTA-trastuzumab.

METHODS

PREPARATION OF 64Cu-DOTA-TRASTUZUMAB
- Trastuzumab (Herceptin® Genentech, Inc.) was conjugated with DOTA (GMP conditions).
- 64Cu-DOTA-trastuzumab was incubated with 64CuCl3 for 45 min at 37°C, chased with DTPA and prepared by size-exclusion HPLC.
- Protein dose of 64Cu-DOTA-trastuzumab injection ≤ 5 mg.
- All doses normalized to ≥ 93%, endotoxin level < 0.05 EU/ml, immunoreactivity > 86%

PATIENT SAFETY
- No adverse events
- Anti-trastuzumab antibody responses
- Possible low-level (< 1 µg/ml) responses seen in 2 patients
- May be followed due to hyperacute expression

PATIENT SAFETY
