LONG-TERM GOALS

Our long term goals are to better understand the interaction of sea ice with the regional and global climate and to improve the skill of predicting the evolution of the ice on daily to decadal time scales.

OBJECTIVES

The overall objective of the proposed research is to collect detailed information about the thermal and physical state of the ice and ocean surface in the Beaufort and Chukchi seas over at least two complete summer melt seasons in order to better understand the physical processes that control the melt, to better represent them in numerical models, and to better predict the seasonal evolution of the ice cover.

APPROACH

The Coast Guard Arctic Domain Awareness (ADA) flights based out of Kodiak Alaska offer a tremendous opportunity to conduct repeated detailed surveys of the sea ice conditions in the Beaufort Sea. ADA flights are conducted twice per month from March through November and offer an especially valuable opportunity in the April-July and October-November periods for which model initialization and evaluation data is critically needed, and ship observations are typically not possible. Therefore, our group proposes to use the ADA flights for Seasonal Ice Zone (SIZ) Reconnaissance Surveys. From the Coast Guard C-130s, we will conduct atmosphere, ice, and ocean observations and buoy deployments from spring into fall in a coordinated experiment with multiple SIZRS observations proposed by various investigators in our team. There will be a set of core measurements needed to 1) make complete atmosphere-ice-ocean column measurements across the SIZ, 2) make a section of ice conditions across the SIZ, and 3) deploy drifting buoys to give time series of surface conditions. The overall SIZRS sampling strategy provides a mix of (i) fixed repeat sections and (ii) flexible sampling depending on ice and ocean conditions.

We propose to design and construct a package of high resolution infrared and visible cameras that can operate on the ADA flights and to then analyze the information obtained to determine the SST, the ice concentration, and the floe size distributions in order to better validate and initialize sea ice prediction models. The fully autonomous Visual-Infrared Package (VIRP) will consist of cameras and associated

instrumentation and data recording equipment. This project will be integrated with the rest of the SIZRS effort and will provide critical measurements of the ice and ocean surface needed for other projects in the group. One goal of the SIZRS project is to create a holistic description of the annual changes of the ocean, ice, and atmosphere in the SIZ with the aim of enhancing predictive capabilities.

Our revised statement or work proposed that we would purchase a high-resolution infrared camera that would be integrated and installed on the CULPIS-X instrument package that is being designed and built by Dr. Mark Tschudi at the University of Colorado. This means that only one instrument package will need to obtain approval from the Coast Guard to be deployed on the aircraft. We would also acquire satellite remote sensing data (MODIS and SSMI) for flight planning before flights and during and after flights for inclusion in the SIZRS-DC database. The CULPIS-X package will be deployed in one of the flare tubes at the year of the aircraft. The figure below shows one of the tubes open.

*Flare tubes on the rear door of a C-130 aircraft where the CULPIS-X instrument package will be installed.*

**WORK COMPLETED**

The CULPIS-X instrument package is still under review and final approval has not yet been obtained. We are delaying the purchase of the high-resolution camera until the final design is set and approval has been secured.

To date, five SIZRS flights have been conducted, one per month starting in May 2012. Below is an example of the MODIS images for the June flight.
MODIS images of the ice pack for the June 2012 flight. The orange line marks the 150W meridian which all of the flights follow.

RESULTS

In collaboration with a second SIZRS project, we have conducted high-resolution WRF model simulations of the weather in the vicinity of the SIZRS flights. A buoy that measures the 2.5-m air temperature and the sea surface temperature was deployed from one of the early flights. The following figure shows the air temperature and skin temperature from the buoy and from the WRF simulations. The WRF SST is prescribed based on the NOAA Reynolds Optimaly-Interpolated SST product. It appears to be biased 2 to 5 C low with respect to the observations. While some of the low frequency variability is captured, some of the shorter term variability isn't. This shows the importance of our future SST work as input to weather and climate investigations. We will be able to better calibrate and evaluate the SST inputs for weather models.
Air and sea-surface temperatures from an air-dropped buoy and from WRF model simulations.

RELATED PROJECTS

This project is part of a broad collaboration of investigators concentrating on using the ADA flights to observe the seasonal ice zone and to investigate the marginal ice zone (where ice and open ocean interact). The following table lists these projects.
