The Ron receptor tyrosine kinase is over-expressed and over-activated in a cohort of human cancers, with the most compelling data yet found in breast cancer. Specifically, Ron is overexpressed in approximately 50% of human breast cancers, and has been shown to be an independent predictor of both metastases and poor prognosis in women with this disease. While Ron overexpression appears to be an important factor in human breast cancer growth and metastasis, a significant gap exists in our knowledge about the signaling pathways that Ron activates in breast tumors, and about the importance of these pathways with respect to overall tumor growth and metastatic dissemination. Our laboratories have shown that mammary tumors from mice overexpressing Ron selectively in the mammary epithelium exhibit increased levels of the Dek proto-oncogene. In addition, we also show that ligand-induced Ron activation in human and murine breast cancer cell lines induces the accumulation of Dek protein. This accumulation of Dek is significant as Dek overexpression in breast cancer cell lines leads to increases in cell growth and migration while Dek depletion in breast cancer cells leads to dramatic reductions in cell growth and migration. Moreover, we also show that Dek deficient cells are more susceptible to DNA damage. Based on these data, our goal is to test the hypothesis that Ron-mediated Dek upregulation contributes functionally to breast cancer development, dissemination and resistance to clastogenic therapies and that targeting the Ron-Dek signaling axis may represent an important new therapeutic option for the treatment of breast cancer. To test this hypothesis, two Specific Aims were proposed. In Aim 1, we will determine the requirement of Dek in Ron overexpressing breast cancers utilizing a combination of Dek loss of function and Ron transgenic overexpression. Aim 2 will examine the therapeutic utility of targeting Ron and Dek on beta-catenin activation and breast cancer growth. The proposed studies are uniquely innovative in many aspects. First, the experiments involve a new murine model of aggressive breast cancer that was developed in the Waltz laboratory, which mimics Ron overexpression observed in human patients. Second, we are using a new Dek knockout mouse model that was characterized and recently reported by the Wells laboratory. Third, the role of Dek in Ron-driven breast cancer, alone or in combination with chemotherapy has not been tested. Fourth, directly assessing the involvement of the Ron-Dek axis in breast cancer is a novel idea as it is unknown if Dek loss will reduce local tumor growth and/or the incidence of metastasis in a relevant in vivo system of breast tumorigenesis. Thus, we feel the new connection of the Ron-Dek signaling pathway and Ron/Dek as therapeutic targets represents a highly innovative area of study which may have an enormous impact on future diagnosis and treatment of patients with breast cancer.

1. INTRODUCTION
The overall goal of our study to test the hypothesis that Ron-mediated Dek upregulation contributes functionally to breast cancer development, dissemination and resistance to clastogenic therapies and that targeting the Ron-Dek signaling axis may represent an important new therapeutic option for the treatment of breast cancer.

2. KEY WORDS
Ron receptor, Dek, beta-catenin, breast cancer

3. ACCOMPLISHMENTS
To meet the goals of this study, two Tasks were outlined in the approved Statement of Work.

Task 1: Determine the functional significance of Dek expression in Ron-driven breast tumorigenesis and tumor response to chemotherapy.

Task 2: Examine the therapeutic utility of targeting Ron and Dek on beta-catenin activation and breast cancer growth.

Task 1
Task 1 was split into two main objectives. The first objective was to define the role of Dek in Ron-driven tumorigenesis, which accomplished during Years 1 and 2. These studies were recently published and a preprint of the manuscript was appended in the last progress report (1). To summarize the information in this publication, our studies identified two commonly overexpressed breast cancer oncogenes, Ron and Dek, which cooperate to promote advanced breast cancer through multipronged stimulatory effects on beta-catenin signaling. We demonstrated that Dek is a downstream target of Ron receptor activation in murine and human models. The absence of Dek in the clinically relevant murine model of breast cancer driven by mammary specific Ron overexpression (MMTV-Ron mice) led to a significant delay in breast tumor development, characterized by decreased cell proliferation, diminished metastasis and fewer cells expressing mammary cancer stem cell markers. Dek expression stimulated the production and secretion of Wnt ligands to sustain an autocrine/paracrine canonical beta-catenin signaling loop. Finally, our data showed that Dek overexpression promoted tumorigenic properties in immortalized human mammary epithelial MCF10A cells and in the context of Ron receptor activation, correlated with disease recurrence and metastasis in breast cancer patients. The results of these studies showed that Dek overexpression, due in part to Ron receptor activation, drives breast cancer progression through the induction of Wnt/beta-catenin signaling. (Initiating and Partnering PIs).

During the course of the analysis of the MMTV-Ron mice, we noted that mammary tumors in this model exhibited upregulation of the Ron ligand, HGFL (hepatocyte growth factor-like protein). While many studies have now established Ron as an important contributor to breast cancer, the necessity of tumor cell produced HGFL had not been investigated (2). Utilizing tissues obtained in the aforementioned studies combined with mammary tumor tissues collected from HGFL deficient MMTV-Ron mice, we demonstrated that HGFL is important for the oncogenic activation of Ron in vivo. We showed that HGFL ablation delayed mammary tumor initiation and that HGFL is a critical factor for mammary tumor cell proliferation and survival. Further, we showed that HGFL loss led to marked differences in the tumor microenvironment of MMTV-Ron tumors correlating with increased macrophage and T-cell recruitment as well as augmented T-cell activation and cytotoxicity. Details of these studies were recently published with the paper appended to this report (2).

The second objective of Task 1 was to generate Ron and Dek modulated mammary tumor cell lines and to examine the function of the Ron-Dek expression in breast cancer growth and chemotherapeutic resistance in vitro and in vivo. During the past year, we generated and characterization mammary tumor cell lines derived from MMTV-Ron mice. Specifically, we generated isogenic mammary tumor cell lines which exhibit high Ron and Dek expression (R7 cells), have a knockdown of Ron (shRon cells) or have a knockdown of Dek (shDek cells) (Figure 1, Left). Viability of these cell lines was first examined in vitro. As shown in Figure 1 (Right), Ron knockdown induced a significant decrease in mammary tumor cell growth compared to control and Dek knockdown cells through 48 hrs of analysis. In cell counting assays, Dek loss was also able to reduce growth...
over time but was not as effective as decreases in Ron expression, likely representing the addiction of the cells to Ron expression (data not shown). The mammary tumor cell lines were then evaluated for their response to the chemotherapeutic agent, cisplatin. As shown in Figure 2, both Ron and Dek knockdown enhanced sensitivity to cisplatin treatment in vitro. Ron knockdown reduced the viability of shRon cells (which already exhibit reduced growth as a result lessened Ron expression) by an additional 34% compared to untreated shRon cells. Similarly, Dek knockdown provided striking increases in sensitivity to cisplatin chemotherapy, likely through deregulation of DNA damage response pathways.

To directly examine the in vivo role of Ron and Dek in breast tumor growth, the R7 modulated mammary tumor cell lines (R7, shRon and shDek) were orthotopically implanted into the mammary glands of immunocompetent FVB mice. Following transplantation, tumor growth was temporally assessed. Figure 3 depicts growth curves of R7, shRon and shDek breast cancer cells in vivo. Knockdown of either Dek or Ron lead to a dramatic reduction in tumor growth. Studies in the next funding period will examine the extent of this growth in combination with chemotherapy treatment.
Task 2
The goal of Task 2 as outlined in the approved Statement of Work was to examine the utility of targeting Ron and Dek on beta-catenin activation and breast cancer growth. We proposed the use of oncolytic viruses containing shRNA to target Dek and the use of neutralizing antibodies to target Ron. As mentioned in the prior progress report, we performed an initial characterization of the 1716HSV Dek knockdown vectors and found that these constructs were not able to efficiently target Dek. We continued to work with Virttu Biologics to design the next generation of 1716Deksh constructs which we anticipated would have the capability to silence Dek expression. During this past funding period, we tested available oncolytic virus to target Dek and and deemed this approach unsuccessful due to the low Dek targeting efficiency. While the 1716HSV platform remains the a viable strategy to therapeutically target the Dek oncogene given that the protein is not yet amenable to small molecule treatment and a crystal structure not available, alternatives for Dek targeting through the use of RNA nanoparticle technology are currently being examined. As we did not obtain substantive results through the oncolytic virus targeting of Dek, we modified our approach to target Dek through genetic manipulation. As such, we knocked down Dek or reconstituted Dek in murine mammary tumor cell lines from MMTV-Ron mice with data reported in Figures 1-3 and (3).

To examine Ron targeting, we chose to inhibit Ron through the use of the small molecule inhibitor BMS-777607 which selectively targets this receptor. In vitro, we demonstrated that BMS treatment of R7 cells dose dependently reduced Ron receptor activation (Figure 4). R7 cells were subsequently implanted into the mammary glands of immunocompetent mice. After the formation of palpable tumors, mice were treated either with vehicle or with BMS for 2 weeks. Tumor kinetics were evaluated temporally and are depicted in Figure 4. Short term BMS treatment was able to effectively suppress mammary tumor growth. These data show that targeting Ron signaling may be an effective approach to limit mammary tumor progression.

Figure 4. BMS selectively targets the Ron receptor and significantly reduces tumor burden. (A) Cultured R7 mammary tumor cells were treated with BMS at the specified concentrations for 2 hours prior to protein lysate collection and analysis of phospho- and total-Ron levels. (B) R7 cells were orthotopically implanted into the fourth inguinal mammary gland of wild-type FVB mice at a density of 1.5x10^5 cells in sterile serum-free media. When tumor sizes reached 50 mm^3 mice were gavaged daily with 75mg/kg BMS dissolved in methocel for 6 days, then 50 mg/kg BMS for an additional 8 days (BMS), or the vehicle control (Ctrl). Tumor growth was monitored regularly for 3.5 weeks. n = 4 mice per group.

Key Accomplishments
- Generated compound mice containing mammary specific Ron overexpression (MMTV-Ron) combined with Dek hetero and homozygosity.
- Initiated procedures to successfully genotype mice from breeding colonies.
- Defined the impact of Dek loss in Ron overexpressing mammary tumors though temporal analysis of tumor kinetics, incidence, and growth.
- Identified by western blot analysis, immunohistochemistry and qRT-PCR the alteration in Wnt ligand induction and in beta-catenin activation in Dek proficient and depleted cells.
• Performed testing of Dek targeted oncolytic viruses and determined that these constructs do not effectively mediate Dek suppression.
• Identification of metastatic and invasive capabilities of Dek overexpression.
• Further data on Dek as an important downstream Ron effector in human and murine breast cancer.
• Determined that Dek and Ron expression cooperate to promote beta-catenin activity and that expression of both genes are highly correlated with breast cancer patient survival.
• Found that high Dek and Ron expression are predictive of early relapse in breast cancer and correlated with a higher risk for developing distant metastases.
• Identified HGFL upregulation in mammary tumors of MMTV-Ron mice and showed that this expression is important for tumor growth and progression.
• Generated mammary tumor cell lines with modifications in Ron and Dek expression.
• Determined that Ron knockdown in murine mammary tumor cell lines leads to decreased cell growth and tumor formation in vitro and in vivo.
• Found that knockdown of Dek in murine mammary tumor cell lines dramatically enhances sensitivity to the chemotherapeutic cisplatin as well as leads to diminished tumor growth in vivo.
• Determined that BMS-777607 is able to effectively target Ron in mammary tumor cell lines and inhibit mammary tumor growth in vivo.

References Cited

4. IMPACT & CONCLUSIONS
  • Our data provide the first direct demonstration that the oncogene Dek is a downstream target of Ron receptor signaling in breast cancer.
  • We demonstrated that the MMTV-Ron murine breast cancer model recapitulates Dek overexpression observed in human breast cancer.
  • The Dek upregulation observed in Ron expressing breast tumors provides a growth and migratory/invasive phenotype to the breast cancer cells.
  • Dek loss in MMTV-Ron mice significantly reduces the time to tumor initiation and is associated with decreased breast cancer cell proliferation.
  • Dek expression controls key molecules involved in Wnt signaling in breast tumors and in breast cancer cell lines.
  • Dek is able to promote breast cancer cell proliferation though the induction of Wnt signaling.
  • Dek expression positively correlates with breast cancer stem cell numbers and mammosphere formation ability.
  • Dek expression is important for breast cancer metastasis in vivo and metastatic phenotypes in vitro.
  • Ron and Dek expression cooperate to promote beta catenin activity and disease progression in primary human breast cancers.
  • Based on studies examining genetic inhibition of Ron and Dek in mammary tumor cell lines, our studies demonstrate that Ron and Dek represent important new targets which may impact breast cancer progression either alone or in combination with chemotherapy.
5. CHANGES/PROBLEMS

- Oncolytic viruses containing shRNA for Dek were produced. Testing of various oncolytic virus constructs did not achieve efficient levels of Dek knockdown. Based on our analysis, the use of oncolytic virus to target Dek does not appear to be an effective approach. Alternative approaches to target Dek will be pursued outside of the scope of this proposal and may include the use of nanoparticle targeting methods.

- We chose to inhibit Ron expression through the use of the small molecule inhibitor BMS-777607 instead of the use of monoclonal antibodies. The change was undertaken as this inhibitor is now in clinical trials and may therefore be clinically relevant. Our preliminary studies demonstrated that BMS was able to effectively inhibit Ron phosphorylation/activation and produced a marked block in tumor growth in vivo.

- Due to delays in obtaining ACURO approval and delays in finding and hiring qualified personal dedicated to performing the research objectives, an additional no cost extension was requested.

6. PRODUCTS

Gene Targeted Animals:
Generated breeding colonies to obtain MMTV-Ron mice that are wild type (+/+), heterozygous (+/-) and deficient (-/-) for Dek.

Cell lines:
Generated several mammary tumor cell lines from MMTV-Ron mice with and without Dek deficiency.

ABSTRACT

The Ron receptor is overexpressed in human breast cancers and is associated with heightened metastasis and poor survival. Ron overexpression in the mammary epithelium of mice is sufficient to induce aggressive mammary tumors with a high degree of metastasis. Despite the well-documented role of Ron in breast cancer, few studies have examined the necessity of the endogenous Ron ligand, hepatocyte growth factor-like protein (HGFL) in mammary tumorigenesis. Herein, mammary tumor growth and metastasis were examined in mice overexpressing Ron in the mammary epithelium with or without HGFL. HGFL ablation decreased oncogenic Ron activation and delayed mammary tumor initiation. HGFL was important for tumor cell proliferation and survival. HGFL loss resulted in increased numbers of macrophages and T-cells within the tumor. T-cell proliferation and cytotoxicity dramatically increased in HGFL deficient mice. Biochemical analysis of HGFL proficient tumors showed increased local HGFL production, with HGFL loss decreasing β-catenin expression and NF-κB activation. Re-expression of HGFL in HGFL deficient tumor cells stimulated cell migration and invasion with coordinate activation of NF-κB and reduced apoptosis. Together, these results demonstrate critical in vivo functions for HGFL in promoting breast tumorigenesis and suggest that targeting HGFL may inhibit tumor growth and reactivate anti-tumor immune responses.

INTRODUCTION

Breast cancer is the most commonly diagnosed cancer amongst women in the US, with approximately 12% of women expected to develop invasive breast cancer during their lifetime [1]. While treatment advances and earlier detection have contributed to a decline in death rates for breast cancer patients, 20 to 30% of patients initially diagnosed with early stage disease will develop metastatic breast cancer, many in spite of successful treatment of a primary tumor, accounting for approximately 40,000 deaths annually [1]. Thus, understanding the mechanisms that contribute to aggressive breast cancer and defining new treatment modalities that have the ability to combat the growth and spread of this disease are needed.

The Ron receptor tyrosine kinase is a member of c-Met family of receptors and is upregulated in many cancers, including breast, prostate and lung [2]. Ron expression is minimally detectable in normal epithelial cells of the mammary gland but is overexpressed in a majority of human breast cancers [2–4]. Importantly, overexpression of Ron in patient samples correlates with poor prognosis and increased metastasis in breast, ovarian and colorectal cancers [5–7]. Similar to human
breast cancers, the feline form of Ron is overexpressed in about 40% of sporadic feline mammary carcinomas, documenting a similar role for Ron overexpression in breast cancers from multiple species [8]. The ligand for Ron is hepatocyte growth factor-like protein (HGFL) [9]. HGFL binding to Ron elicits tumorigenic potential by regulating epithelial cell proliferation, motility, adhesion and anoikis [10–13]. Studies from our laboratory were the first to demonstrate a functional significance for Ron in breast cancer, with loss of Ron signaling delaying tumor initiation, growth and metastasis [14]. To determine if Ron overexpression could be causative in disease progression, mice that overexpress Ron selectively in the mammary epithelium (MMTV-Ron mice) were generated [4]. In these animals, Ron overexpression was sufficient to induce aggressive breast tumors that were highly metastatic. All female mice developed breast tumors, with the majority exhibiting lung and liver metastases. Further studies have shown that Ron elicits its tumorigenic potential in vivo through the activation of downstream signaling pathways, including β-catenin, PI3K/Akt, MAPK, STAT3 and NF-κB [14–18]. Ron’s activation of β-catenin was shown to be important for breast tumor onset, growth and metastasis, with activation of NF-κB critical for regulating tumor cell survival and angiogenesis [4, 17–19]. Thus, mounting evidence indicates that Ron overexpression is a causative factor contributing to aggressive breast cancer and metastatic disease.

Ron expression is also found on tissue resident macrophages [16, 20–25] and its activity has been associated with resolving the inflammation and supporting tissue healing after activation of the innate immune system [24, 26–29]. Recent studies have examined the importance of Ron in the polarization of tumor-associated macrophages (TAMs), where Ron signaling loss initiates a switch from a pro-tumorigenic (M2) polarization state to a classical or inflammatory (M1) state [16, 30], leading to a decrease in tumor burden. Decreased tumor growth was associated with enhanced numbers of CD8+ cytotoxic T-cells within the tumor microenvironment. Further, antibody depletion of CD8+ T-cells was able to restore aggressive tumorigenesis [16], indicating that Ron signaling in tumor-associated macrophages influences CD8+ cytotoxic T-cell activities although the mechanisms associated with this effect are not known.

HGFL shares a similar domain structure to hepatocyte growth factor (HGF). HGF is a fibroblast-derived growth factor that acts in a paracrine as well as autocrine manner to activate the c-Met receptor [31]. HGFL is primarily produced by hepatocytes and is secreted into the circulation, acting in an endocrine manner to stimulate Ron. While there is an abundance of studies regarding HGF activity, only a few reports have examined the importance of HGFL. Ectopic overexpression of HGFL in mammary tumor cells derived from polyoma middle T-antigen expressing mice promoted early tumor growth and broadened the spectrum of metastasis compared to control tumor cells [7]. Additionally, ectopic overexpression of HGFL increased metastasis of small cell lung carcinoma cells [32]. Although these studies suggest an important function for the overexpression of HGFL in tumor growth and metastasis, they fail to decipher the physiological relevance of endogenous levels of HGFL in tumorigenesis and metastasis. Prior studies in this area have shown that while HGFL deletion in normal mice does not affect circulating blood counts or differentials, examination of normal mammary gland development in HGFL−/− mice suggest that HGFL may play an important role as a chemoattractant for macrophages, with loss of HGFL associated with alterations in macrophage recruitment to the terminal end bud of the developing mammary gland [39].

Here, we show that MMTV-Ron mice lacking HGFL (MMTV-RonHGFL−/− mice) have a significant delay in the development of mammary hyperplasia and mammary tumor onset. This delay precedes a reduction in tumor size and reduced metastatic burden in the MMTV-RonHGFL−/− mice. Moreover, HGFL deficient tumors exhibited decreased cell proliferation and angiogenesis as well as increases in tumor cell death compared to HGFL proficient tumors. In vitro examination of epithelial cells derived from MMTV-RonHGFL−/− mice recapitulates the in vivo tumor cell intrinsic decreases in survival, migration and invasion compared to HGFL replete cells. Further, we show that cytotoxic T-cells are influenced by loss of HGFL, with T-cells from MMTV-RonHGFL−/− mice displaying increased proliferation and more efficient killing. In total, this study highlights the importance of HGFL in oncogenic Ron activation and mammary tumorigenesis through the regulation of both the primary tumor and the tumor microenvironment.

RESULTS

HGFL ablation delays the onset of mammary hyperplasia in MMTV-Ron mice

To determine whether loss of HGFL changes kinetics of mammary tumorigenesis in MMTV-Ron mice, the MMTV-RonHGFL+/+ mice were crossed to HGFL−/− mice. HGFL−/− mice are phenotypically normal with no differences observed in the number or morphology of circulating blood cells or platelets compared to control mice [33]. The contribution of HGFL on the incidence and development of hyperplasia was examined by isolating inguinal mammary glands at 2.5, 4, 6, 8 and 10 months from MMTV-RonHGFL+/+ and MMTV-RonHGFL−/− mice. The presence of ductal hyperplasia was identified by mammary whole mount and histological analyses of glands from both genotypes (Figure 1). By 4 months of age, 75% of the MMTV-RonHGFL+/+ mice exhibited ductal hyperplasia and by 8 months, all mammary glands from MMTV-RonHGFL−/− mice displayed hyperplasia. In contrast, by 8 months of
age, only about 50% of the MMTV-RonHGFL−/− glands contained hyperplastic nodules and a significant difference in the median time to the development of hyperplasia was also noted between groups (Figure 1A). Representative whole mounts and histological sections at 8 months for each group are shown in Figure 1B. To further examine the role of HGFL in tumor progression, ductal invasion (defined as tumor cell invasion through the basement membrane) was quantified by determining the number of ducts with invasive carcinoma by histological analysis. Similar to the hyperplasia data, a significant decrease in local tumor cell invasion was apparent in the mammary glands of MMTV-RonHGFL−/− mice at 4 and 6 months compared to MMTV-RonHGFL+/+ mice (Figure 1C).

Figure 1: Mammary glands from MMTV-RonHGFL−/− mice exhibit delayed hyperplasia and invasive ductal carcinoma. A. Quantification of mammary hyperplasia observed in inguinal mammary glands by whole mount and H&E analyses at 2.5, 4, 6, 8 and 10 months in MMTV-RonHGFL+/+ and MMTV-RonHGFL−/− mice (n = 28–34/genotype). MMTV-RonHGFL−/− mice have a significant delay in the development of mammary hyperplasia, with a median time to hyperplasia at 240 days compared to 120 days in the MMTV-RonHGFL+/+ mice, *P < 0.05. B. Representative mammary whole mounts and H&E sections from 8-month-old MMTV-RonHGFL+/+ and MMTV-RonHGFL−/− mice. Scale Bar 100 μM. C. Quantification of invasive ductal carcinoma at 4 and 6 months. MMTV-RonHGFL−/− mice have significantly reduced local tumor invasion compared to MMTV-RonHGFL+/+ mice (n = 20–30 sections per genotype per time point from 4–6 mice each). *P < 0.05.
HGFL loss impedes mammary tumor formation and metastatic dissemination in MMTV-Ron mice

The time to palpable tumor formation was followed in mice of each genotype. Although all mice developed mammary tumors, MMTV-Ron<sup>HGFL<sup>-/-</sup></sup> mice had a significant delay in the time to detection of palpable mammary tumors (Figure 2A). A significant increase in the median time to palpable tumor detection in MMTV-Ron<sup>HGFL<sup>-/-</sup></sup> mice was observed compared to MMTV-Ron<sup>HGFL<sup>+/+</sup></sup> mice (Figure 2A, inset). Tumor architecture, as examined by H&E staining, did not differ between groups (Figure 2B).

To examine HGFL loss, Western analysis was performed on mammary tumor lysates from both genotypes. HGFL protein was detected in tumors from MMTV-Ron<sup>HGFL<sup>-/-</sup></sup> mice (Figure 2C). Interestingly, HGFL mRNA expression was also observed in mammary tumors from MMTV-Ron<sup>HGFL<sup>-/-</sup></sup> mice suggesting that HGFL may be locally produced during mammary tumor progression.

Figure 2: Mammary tumorigenesis is significantly delayed and metastasis reduced in MMTV-Ron<sup>HGFL<sup>-/-</sup></sup> mice.

A. MMTV-Ron<sup>HGFL<sup>-/-</sup></sup> mice (<i>n</i> = 19) have a significant delay in palpable tumor formation and the median time to palpable tumors (inset) compared to MMTV-Ron<sup>HGFL<sup>+/+</sup></sup> mice (<i>n</i> = 29). B. Representative histological images of mammary tumors from MMTV-Ron<sup>HGFL<sup>-/-</sup></sup> and MMTV-Ron<sup>HGFL<sup>-/-</sup></sup> mice are shown and were taken when tumors represented approximately 10% of body weight in each genotype. C. Mammary tumors from MMTV-Ron<sup>HGFL<sup>-/-</sup></sup> express HGFL protein while MMTV-Ron<sup>HGFL<sup>-/-</sup></sup> mice do not as depicted by Western analyses of tumor lysates. Tubulin is shown as a loading control. Both processed (active) and pro-HGFL are present in the mammary tumors of HGFL expressing mice. D. HGFL mRNA is expressed in MMTV-Ron<sup>HGFL<sup>-/-</sup></sup> mammary tumors while tumors from HGFL deficient animals do not express HGFL. (<i>n</i> = 5–6/glands from independent mice were examined/genotype). E. Oncomine data shows that HGFL expression is increased in ductal breast carcinoma compared to normal mammary gland. *<i>P</i> < 0.05. ND, not detectable.
(Figure 2D). To determine if HGFL expression is observed locally in human breast cancer, the Oncomine database was examined. Figure 2E depicts HGFL mRNA expression levels significantly upregulated in breast carcinomas compared to normal breast tissue [34]. Interestingly, examination of the cBioPortal datasets showed a significant co-occurrence of Ron and HGFL in breast cancer as well as in other cancer types. Further, in breast cancer, this database lists multiple mutations in HGFL that are associated with reduced survival (83.3 vs. 122.8 months in patients with and without a mutation respectively) [35, 36].

MMTV-Ron<sup>HGFL<sup>−/−</sup></sup> mice exhibit a high metastatic burden [4] and a comparative analysis of metastasis was performed between genotypes. A significant reduction in the size of the metastatic foci in the lungs was found in the MMTV-Ron<sup>HGFL<sup>−/−</sup></sup> mice compared to MMTV-Ron<sup>HGFL<sup>+/+</sup></sup> mice, with representative lung metastatic foci from the MMTV-Ron<sup>HGFL<sup>−/−</sup></sup> mice at 6 months compared to the smaller MMTV-Ron<sup>HGFL<sup>−/−</sup></sup> lung foci observed at 8 months (Figure 3A). In the liver, a significant reduction in the number of mice with liver metastasis was observed at all stages examined in HGFL deficient mice, with less than 60% of the MMTV-Ron<sup>HGFL<sup>−/−</sup></sup> livers displaying metastatic foci at 10 months (Figure 3B) compared to controls with 100% of mice exhibiting liver foci by 6 months of age. Accordingly, MMTV-Ron<sup>HGFL<sup>−/−</sup></sup> exhibit reduced expression of N-Cadherin and Vimentin, markers of epithelial to mesenchymal transition (EMT). (Figure 3C).

HGFL deficient tumors have decreased proliferation, increased cell death and reduced angiogenesis

To examine the mechanism behind the delay in mammary tumorigenesis in the MMTV-Ron<sup>HGFL<sup>−/−</sup></sup> mice, mammary tumor sections, from mice when tumors were at similar sizes, were examined for the extent of mammary tumor cell turnover by BrdU and TUNEL staining. MMTV-Ron<sup>HGFL<sup>−/−</sup></sup> mammary tumors had significantly more proliferation based on BrdU incorporation than MMTV-Ron<sup>HGFL<sup>−/−</sup></sup> mice (Figure 4A). Mammary tumors from MMTV-Ron<sup>HGFL<sup>−/−</sup></sup> mice had a significant increase

Figure 3: Lung and liver metastases are reduced in MMTV-Ron<sup>HGFL<sup>−/−</sup></sup> mice. Lung and liver metastases were quantified by histological analysis at 6, 8, and 10 months of age. A. Lung tumor metastasis was significantly reduced in MMTV-Ron<sup>HGFL<sup>−/−</sup></sup> mice with the size of metastatic foci in MMTV-Ron<sup>HGFL<sup>−/−</sup></sup> mice significantly smaller compared to controls. The images show a representative metastatic lesion in the lungs of a MMTV-Ron<sup>HGFL<sup>+/+</sup></sup> mouse at 6 months while the image for MMTV-Ron<sup>HGFL<sup>−/−</sup></sup> is from 8 months (n = 5–10/group and time point). Scale bar = 100 μM. B. The incidence of liver metastases was significantly reduced in MMTV-Ron<sup>HGFL<sup>−/−</sup></sup> mice at 6 and 10 months of age (n = 5–10/group and time point). C. Mammary tumor tissue was examined by qRT-PCR for expression of EMT genes. N-cadherin and vimentin were significantly down regulated in MMTV-Ron<sup>HGFL<sup>−/−</sup></sup> mice (n = 3–4grp). *P < 0.05.
in TUNEL positive cells compared to tumors from MMTV-RonHGFL+/+ mice (Figure 4B). Angiogenesis was also significantly blunted in the MMTV-RonHGFL−/− as indicated by CD31 staining of vessels (Figure 4C). These data suggest that loss of HGFL signaling influences tumor development through multiple mechanisms.

**Tumors from MMTV-RonHGFL−/− mice exhibit significant alterations in the tumor microenvironment**

As Ron is a known player in macrophage function, the distribution and activation status of tumor-associated macrophages was examined. A significant increase in F4/80 positive macrophages was measured in tumor sections from MMTV-RonHGFL−/− mice compared to controls (Figure 5A). This increase corresponded with a significant decrease in Arginase 1 staining (a M2 marker) and an increase in iNOS staining (a M1 marker), suggesting that loss of Ron signaling due to ligand deletion modifies tumor-associated macrophages toward a pro-inflammatory phenotype. These findings were further substantiated utilizing qRT-PCR, wherein mammary tumor samples from MMTV-RonHGFL−/− mice showed a significant increase in pro-inflammatory cytokine expression (Figure 5B). Along with the increase in M1 macrophage marker message expression, T-cell recruitment signals (CXCL9) along with co-stimulatory molecules (CD80/CD86) were increased in MMTV-RonHGFL−/− tumors (Figure 5B). These data suggest changes in macrophage polarization may drive changes in T-cell recruitment into the tumors of MMTV-RonHGFL−/− mice. This notion is supported by IHC data that shows

**Figure 4:** Mammary tumors from MMTV-RonHGFL−/− mice exhibit significantly reduced proliferation, increased cell death and reduced vessel staining. Quantification of mammary tumor sections and representative images of BrdU, TUNEL and CD31 stained sections. A. MMTV-RonHGFL−/− mice have significantly reduced number of proliferating tumor cells compared to MMTV-RonHGFL+/+ tumors (n = 3 fields per mouse, 4 mice/group). B. Mammary tumors from MMTV-RonHGFL−/− mice exhibit significantly more cell death than tumors from MMTV-RonHGFL+/+ mice (n = 3 fields per mouse, 4 mice/group). C. Quantification of CD31 staining shows a significant reduction in vessel density in MMTV-RonHGFL−/− tumors compared to MMTV-RonHGFL+/+ tumors. (n = 3 fields per mouse, 4 mice/group). *P < 0.05, Scale bar = 100 μM.
a significant increase in CD8+ T-cells in tumors from HGFL deficient mice compared to controls (Figure 6A). To examine the proliferative capacity of the CD8+ T-cells, a subset of mice were injected with EdU 14 hours prior to euthanasia. Tumors were dissociated and isolated CD8+ T-cells were analyzed for EdU incorporation by flow cytometry. Figure 6B shows a significant increase in the percentage of EdU positive CD8+ T-cells in MMTV-RonHGFL−/− mice compared to HGFL expressing mice. Further, tumor-associated CD8+ T-cells from MMTV-RonHGFL−/− mice express more CD3e receptor, a marker of activation, than CD8+ T-cells from mammary tumors from MMTV-RonHGFL+/+ mice (Figure 6C). To investigate changes in T-cell activity, splenocytes from tumor-bearing mice were utilized. Splenocytes isolated from tumor bearing MMTV-RonHGFL−/− mice exhibited significant increases in T-cell proliferation ex vivo (Figure 6D). Further,
when cultured along with R7 tumor epithelial cells (derived from a mammary tumor from MMTV-Ron mouse), splenic-derived T-cells from MMTV-RonHGFL−/− mice had increased cytotoxic activity compared to cells from MMTV-RonHGFL+/+ mice as judged by a reduction in overall mammary tumor cell number (Figure 6E). Together, these data suggest that loss of HGFL leads to changes in macrophage polarization which alter the tumor microenvironment through increased recruitment, activation and cytotoxic function of CD8+ T-cells.
Ron kinase activity is significantly reduced in MMTV-Ron$^{HGFL−/−}$ mice, leading to diminished NF-κB and β-catenin signaling

To determine if activation of Ron is affected by HGFL loss, Ron kinase activity and phosphorylation status in mammary tumors from MMTV-Ron$^{HGFL+/+}$ and MMTV-Ron$^{HGFL−/−}$ mice was examined. Kinase assays were performed with equal amounts of Ron immunoprecipitated from mammary tumor lysates of MMTV-Ron$^{HGFL+/+}$ and MMTV-Ron$^{HGFL−/−}$ mice. Ron from MMTV-Ron$^{HGFL+/+}$ tumors robustly phosphorylated an exogenous substrate (myelin basic protein, MBP) compared to Ron from MMTV-Ron$^{HGFL−/−}$ tumors (Figure 7A–7B). Ron kinase activity was approximately 10-fold more active from HGFL replete mice compared to HGFL deficient mice.

**Figure 7:** HGFL loss blunts Ron activation in mammary tumors from MMTV-Ron mice, leading to down regulation of β-catenin and the NF-κB pathway. A. Ron activation status was determined by immunoprecipitating Ron from mammary tumor lysates from MMTV-Ron$^{HGFL+/+}$ and MMTV-Ron$^{HGFL−/−}$ mice and through kinase assays evaluating the ability of Ron to phosphorylate myelin basic protein (MBP). A representative image showing the extent of phosphorylated (p)MBP detected by autoradiography is shown. Western analysis of the amount of immunoprecipitated Ron (INPUT) and Ron phosphorylation (pRon) is shown. B. Graph shows quantification of Ron kinase activity from three independent kinase assays with $n = 3$ samples per group in each assay. The kinase activity is normalized to total immunoprecipitated Ron. C. Densitometric analysis of phosphorylated Ron over total Ron protein levels from mammary tumors from MMTV-Ron$^{HGFL+/+}$ and MMTV-Ron$^{HGFL−/−}$ mice. D&E. Western analysis of mammary tumor lysates from MMTV-Ron$^{HGFL+/+}$ and MMTV-Ron$^{HGFL−/−}$ mice for β-catenin and NF-κB pathway mediators D, and cleaved caspase 3 E. Actin serves as a loading control. F. Graphs show protein expression normalized to Actin or total protein by quantification of Western blot analyses ($n = 4–6$ mice per group). *$P < 0.05.$
mice. Further, a significant increase in the amount of phosphorylated Ron (Y1238/Y1239) receptor was found in MMTV-RonHGFL+/− mammary tumors as compared to MMTV-RonHGFL−/− tumors (Figure 7A, 7C).

Previous studies have demonstrated that β-catenin loss in MMTV-Ron mice delays the onset of mammary hyperplasia, time to palpable tumor formation and results in decreased metastasis [18, 37]. Additional studies have shown that in vivo tumor cell survival requires Ron-dependent NF-κB activation [17]. As the kinase activity and phosphorylation status of Ron were significantly reduced in the mammary tumors of the MMTV-RonHGFL−/− mice, the expression of downstream signaling pathways regulated in response to HGFL-mediated Ron activation was examined. Mammary tumor lysates from MMTV-RonHGFL+/− and MMTV-RonHGFL−/− mice were isolated and subjected to Western analysis. MMTV-RonHGFL−/− mammary tumors exhibited significantly reduced β-catenin levels compared to MMTV-RonHGFL+/− tumors. While no appreciable differences were observed in the activation of Akt, MAPK or STAT3 in the tumor lysates between genotypes (data not shown), several components of the NF-κB pathway were modified in MMTV-RonHGFL−/− tumors. Phosphorylated NF-κB was significantly decreased along with total and phosphorylated IκKα/β in the MMTV-RonHGFL−/− tumors compared to MMTV-RonHGFL+/− controls (Figure 7D). Cleaved caspase 3 was also increased in MMTV-RonHGFL−/− tumor lysates (Figure 7E), supporting the results of TUNEL staining in Figure 4B. Figure 7F depicts quantification of Western blot analyses. These data suggest that activation of the NF-κB pathway is dependent on HGFL-mediated Ron signaling and may drive changes in apoptosis.

**DISCUSSION**

There are mounting reports implicating the Ron receptor tyrosine kinase in breast cancer progression and metastasis. However, there is scant information on whether Ron activation in this context requires its ligand, HGFL. Limited studies have highlighted the importance of HGFL in tumor models, including the mammary gland using ectopic overexpression [7, 32]. However, a major limitation of overexpression studies is that they do not investigate function within a physiological context. The study presented here is the first to examine the role of endogenous HGFL in the context of Ron overexpression, a condition associated with poor prognosis in human tumors [7]. In support of this data, mammary gland specific overexpression of HGFL (the ligand for c-Met) in transgenic mice induces mammary hyperplasia that progressed to form invasive mammary tumors compared to wild type mice [38]. Akin with overexpression studies, our data demonstrates the importance of HGFL in promoting ductal hyperplasia and progression to tumorogenesis in MMTV-Ron mice. Additionally, HGFL overexpressing mammary tumors led to increased phosphorylation of the c-Met receptor [38]. Similarly, decreased phosphorylation and activity of the Ron receptor was observed in MMTV-RonHGFL−/− tumors compared to MMTV-RonHGFL+/− tumors. These data highlight the importance of endogenous HGFL in Ron activation during mammary tumorigenesis.

Previous studies have documented that Ron or HGFL overexpression is associated with heightened metastasis [4–7, 15]. In this report, both local invasion as well as metastatic dissemination was examined temporally. Interestingly, evidence of tumor cells invading into the surrounding mammary gland (invasive ductal carcinoma) were identified in both MMTV-RonHGFL+/− and MMTV-RonHGFL−/− glands as early as 4 months. However, MMTV-RonHGFL+/− mice had a significantly higher percentage of ducts exhibiting local invasion at all measured time points compared to MMTV-RonHGFL−/− animals. Consistent with the high invasive capacity of Ron expressing mammary tumors, 100% of mice examined in the MMTV-RonHGFL+/− group had metastasis to the lungs and liver at 8 and 10 months. In comparison, significantly fewer MMTV-RonHGFL−/− mice had liver metastasis at these time points.
(50% at 6 months and 60% at 10 months). While the incidence of lung metastases was similar between groups, metastatic foci were significantly smaller in the MMTV-RonHGFL−/− lungs compared to lungs from MMTV-RonHGFL+/+ mice. These results are similar to that reported in the polyoma middle T-antigen expressing mouse mammary tumor model, where ectopic overexpression of HGFL led to an increased metastatic burden compared to control mice [7]. Further studies have shown that Huh7 liver cells treated with exogenous HGFL display
epithelial-mesenchymal transition (EMT) markers in vitro [40], consistent with the data herein demonstrating reduced EMT marker expression in HGFL deficient tumors compared to HGFL replete tumors. Together, these data highlight the importance of endogenous HGFL in the activation of Ron in cancer cell invasion and metastasis.

An interesting finding of these studies was the alterations observed in the tumor microenvironment. In the current study, loss of HGFL regulated the recruitment and polarization of tumor-associated macrophages, similar to recent studies using Ron signaling deficient mice showing decreased tumor burden associated with increased M1 macrophage infiltration and cytotoxic T cell activity [16, 30]. With loss of Ron signaling, the tumor-associated macrophages expressed markers of classically activated (M1) macrophages and were associated with significant increases in proinflammatory cytokines, as well as markers of cytotoxic T-cells. T-cell numbers were significantly increased in MMTV-RonHGFL−/− mice, with tumor-associated CD8+ T-cells proliferating more than those from MMTV-RonHGFL+/+ mice. Further investigation showed increased cytotoxic activity of T-cells in the MMTV-RonHGFL−/− mice. Increases in tumor-infiltrating lymphocytes, including CD8+ T-cells, are widely associated with improved outcomes in human breast cancer patients [41–45].

In addition to immune cells, HGFL loss also had a profound effect on the formation of vessels within the tumor microenvironment. These results are similar to published studies that describe Ron expression in the tumor proper as a promoter of tumor angiogenesis. In vitro, knockdown of Ron expression in prostate cancer cells reduced the production of angiogenic chemokines (CXCL1, 5 and 8) leading to a decrease in endothelial cell migration [19]. Correspondingly, in vivo implantation of Ron knockdown cells in mouse xenograft experiments lead to decreased tumor growth and angiogenesis compared to Ron expressing cells. Further, conditioned media from Ron expressing pancreatic cells induced microtubule formation in human microvascular endothelial cells [46]. Together these data show that activation of Ron signaling within tumor cells plays an important role in mediating vessel formation in the growing tumor. Similarly, our data show a decrease in CD31 staining in MMTV-RonHGFL−/− mice, indicative of reduced vessel density compared to control mice.

The data herein are the first to suggest that HGFL is playing an important role in cross talk between multiple cell types within the tumor microenvironment. As the Ron receptor is a target of broad-spectrum kinase inhibitors and specific antibodies currently in clinical trials, our data provide strong pre-clinical support for targeting this signaling pathway and more specifically for targeting HGFL in breast cancer. Further, targeting of HGFL-Ron signaling may provide the signals needed to reactivate the anti-tumor immune response, leading to an effective therapy for breast cancer and other Ron expressing tumor types.

Many pathways are activated by the Ron receptor tyrosine kinase, including β-catenin PI3K/Akt, MAPK, NF-κB and STAT3. In the context of this study, loss of HGFL under conditions of Ron overexpression led to alterations in the NF-κB pathway and a reduction in β-catenin. β-catenin is a component of the Wnt signaling pathway and is critical for multiple cell functions. HGFL dependent Ron signaling has been shown to stimulate β-catenin nuclear localization and transcriptional activity in human and mouse breast cancer cell lines in vitro and in vivo [18, 37, 47]. The results described herein extend these observations and further strengthen the connection between Ron signaling and β-catenin, whose deregulated expression is associated with poor prognosis in breast cancer. These data are consistent with published studies showing β-catenin nuclear accumulation in WAP-HGF mammary tumors [38], suggesting a strong association between HGFL expression and β-catenin signaling.

The NF-κB signaling pathway is known to activate a vast number of target genes, generally thought as pro-survival factors which support cancer development [48]. Knockdown of Ron signaling using siRNA in prostate tumor cell lines showed increased accumulation of the NF-κB inhibitory protein IκBα as well as reduced NF-κB activity [19]. These changes were associated with a reduction in angiogenic chemokines and reduced vessel density. Our data show a reduction of the NF-κB pathway through reduced NF-κB and IκKa/β phosphorylation as well as reduced CD31 staining. The reduction of NF-κB signaling suggests reduced activation of downstream target genes. Some of these target genes include those involved in apoptosis, such as X-link inhibitor of apoptosis protein (XIAP), an inhibitor of caspase-3 and 7 [49]. An increase in cleaved caspase-3 protein was observed in mammary tumors of MMTV-RonHGFL+/+ mice compared to MMTV-RonHGFL−/− mice, along with increased apoptosis as measured by TUNEL assays. These data are supported by in vitro HGFL re-expression assays in HGFL deficient cells, where HGFL expression lessened cleaved caspase-3 protein expression and apoptosis measured by Annexin V/PI flow cytometry. In the context of mammary tumorigenesis, our results suggest that HGFL may promote mammary tumorigenesis and metastasis through a mechanism associated with increased tumor cell survival mediated by NF-κB and β-catenin signaling.

Importantly, this is the first study to describe the tumor cell autonomous production of HGFL from mammary tumors cells. Recent publications from our group have shown that HGFL expression is present in the developing mammary gland as well as in prostate tumor cells [39, 50]. In this study, we demonstrate heightened HGFL mRNA expression during tumorigenesis. The source of local HGFL production is the tumor epithelial cells, which was confirmed in cell lines derived from Ron overexpressing tumors. As the liver maintains circulating HGFL at a high concentration, the production of locally derived HGFL suggests that local HGFL...
may play a crucial role in tumorigenesis by influencing multiple cell types within the tumor microenvironment. Functionally, studies in this report demonstrate that tumor cell autonomous HGFL production, in isolated mammary tumor epithelial cells, is sufficient for enhanced invasion, migration and survival in vitro. These in vitro studies clearly support the in vivo findings of decreased metastatic capability of mammary tumor cells lacking HGFL as well as reduced EMT gene expression in metastatic capability of mammary tumor cells lacking HGFL. We describe changes within immune cells in tumors as well as isolated mammary epithelial cells in tumor burden is associated with increased apoptosis which additional tumor models and human tumors exhibit HGFL upregulation and invasive growth remains to be determined.

The regulation of Ron activation and subsequent signaling by HGFL represent a novel and specific target for cancer therapeutics. The only known receptor for HGFL is Ron and despite sequence homology, HGF and HGFL are not cross-reactive [9]. As such, HGFL is an attractive therapeutic candidate for targeting the Ron receptor pathway. Several broad-spectrum receptor tyrosine kinase inhibitors with some affinity for Ron are already in phase I-II clinical trials. These drugs have shown effectiveness in preclinical models [51, 52] and Foretinib has been shown to reduce phosphorylation of Ron in human patient samples [52]. The data presented here clearly implicate the importance of HGFL for Ron activation and subsequent tumorigenesis. The data presented here provide the rationale for the development of targeted therapies that inhibit HGFL binding and subsequent activation of Ron.

**MATERIALS AND METHODS**

**Generation of mice**

To generate MMTV-RonHGFL+/−, FVB female HGFL−/− mice (backcrossed 9 generations to FVB) [33] were crossed to FVB MMTV-Ron positive males. The resultant heterozygous males (MMTV-RonHGFL+/−) were backcrossed to HGFL+/− females to generate the females used in this study. Female mice were maintained as described previously [4]. Genotyping of transgenic mice was performed by PCR analysis. Primers sets for identification of MMTV-Ron and HGFL−/− mice are as follows: MMTV-Ron forward 5′-TGG GTG TG TG AGG TCT GCC AAC ATG A-3′, reverse 5′-CCG TCT TCG GGA GTT AAA GAT CAG GG-3′. For HGFL, the following 3 primers were utilized: 5′-AAT CTG GGT TGC CAG TTA ACT TTG TGT -3′, 5′-AAG TTC TCT TCC AGG CCA TTC TTT GCC-3′, 5′- GGA AAA GCG CCT CCC CTA CCC GG-3′.

**Mammary tumor initiation and progression**

Females were palpated weekly to assess mammary tumor development as previously described [4]. At the designated time points, frozen and formalin fixed tissues were collected from thoracic and inguinal mammary glands, lungs and liver. All animal procedures were approved by the University of Cincinnati Institutional Animal Care and Use Committee.

**Cell culture**

Mammary epithelial tumor cell lines from MMTV-RonHGFL+/− mice (R7 cells) and MMTV-RonHGFL−/− mice (H44 cells) were derived as previously described [4, 53]. H44 cells were infected with lentiviral vector constructs designed to re-express HGFL (H44e). HGFL secretion from stably transduced cells was verified using western analysis (described below).

**In vitro assays**

All assays were performed in triplicate and repeated at least 3 times. Boyden chambers were used for migration and invasion assays, with the addition of 1:1 matrigel: media (BD Biosciences, San Jose, CA) coating the top well for invasion assays. MTT (3-(4, 5-Dimethylthiazol-2-yl)-2, 5-diphenyltetrazolium bromide, Sigma Aldrich, St, Louis, MO) was used to quantify cell viability at 0, 24 and 48 hours. Annexin V and propidium iodide...
(BD Biosciences) staining was used to measure cell death on serum-starved cells at 24 hours.

**Tissue histology**

Tissues were processed as described previously [4]. Briefly, mammary glands, lungs, and liver samples were fixed, paraffin embedded, and cut into in 4 μm sections. Sections were stained with hematoxylin and eosin for routine histological examination. Whole mount analysis was completed as previously described [4].

For BrdU analysis, mice were injected with 5-bromo-2’-deoxyuridine (BrdU) 2 hours prior to euthanasia and immunohistochemistry was performed as previously described [54]. In Situ Apoptosis Detection Kit (EMD Millipore, Billerica, MA) was used according to the manufacturer’s instructions for TUNEL staining. For both proliferation and apoptosis, quantification of positive epithelial cells at 400X magnification was completed by counting at least three independent fields per slide from at least three different tumors from each group.

Standard procedures were used for staining of F4/80 (eBiosciences, San Diego, CA), Arginase I (BD), iNOS (BD Biosciences) and CD8α (BD Biosciences), with the number of positive cells counted at least three independent fields per slide from at least three different tumors per group. CD31 (Dako, Carpinteria, CA) was stained using standard procedures and qualified using image J software to calculate area stained in at least three independent fields per slide from at least three different tumors from each group.

**Kinase assays, western blotting and quantitative real time (qRT)-PCR**

Kinase assays were performed according to published protocols [4]. In brief, Ron was immunoprecipitated from 500 μg mammary tumor lysates from MMTV-RonHGFL+/+ and MMTV-RonHGFL−/− mice with 2 μg of primary antibody (anti-Ron C-20, Santa Cruz Biotechnology, Santa Cruz, CA, USA). Equal amounts of immunoprecipitated Ron were placed in a kinase reaction with equal concentrations of myelin basic protein (MBP) (Millipore, Billerica, MA, USA) as substrate and [γ-32P]-ATP as the phosphate donor. Following incubation, samples were separated using sodium dodecyl sulfate–polyacrylamide gel electrophoresis and the gels were fixed, dried and imaged on a phosphoimager to detect labeled MBP. Kinase activity was normalized to total immunoprecipitated Ron following Western analysis (INPUT) of immunoprecipitated Ron. For measurement of secreted HGFL, cells were seeded at an equal density and incubated for 36 hours in serum free media. The conditioned media from these cells was collected and concentrated using Amicon Ultracel filter units with 3kD membranes (EMD Millipore). For total tissue lysates, the following antibodies were used: phospho-NF-κB, phospho-Iκκα/β, total NF-κB, total IKK, cleaved caspase-3, phospho-Stat3, and β-catenin (Cell Signaling Technology, Danvers, MA) as well as HGFL (Santa Cruz Biotechnology, Dallas, TX). β-Actin (Cell Signaling) or α-tubulin (Santa Cruz) expression was measured as a loading control. qRT-PCR was performed as previously described [25] and primer sets used are as follows:

18S (AGTCCCCCTGCGCTTTGTACACA, GATCC GAGGG CCTCCTCAAAAC);

CD80 (ACCCCCAACATACTGAGTCT, TTCCAACC AAGAGAGGAGG);

CD86 (CTTACCGGAGCCACCCACGT, TCTCCAGGG AAACAGCATCT);

CXCL9 (GGAGTTGAGGAAACCCCTAGTG, GGATTT GTAGTGAGTCCTG);

CXCR3 (TACCTTGAGGTTAGTGACGTCA, CGCTC TCCTTTCCCCATAATC);

HGFL (GCTGTTGGCATCAAAACCT, TGGAAAGGTT GCGAT);

iCOS (TGACCCACCTCTTCTTCAAG, TTAGGGTCAT GCACACTGGA);

TNFα (GGTCCCCAAAGGGAGTGAGAA, CTCCAGCT GCTCCTCACTTT);

Vimentin (CCCAACCTTTTTCTTCTTGA, TGAAGTG GGTCTGACCTCAAG);

N-Cadherin (AGGCCAGTCCTTACCCAGAG, TCGCTG CTCTCTACTGACCTT);

IFNγ (GATATCTCGAGGAGCTGGAAAAAA, CTTCCAA GAGTCTGAGGAGATACAT).

**T-cell isolation and EdU analysis**

For EdU analysis of tumor associated CD8+ T-cells, mice were injected with 5-ethynyl-2’-deoxyuridine (EdU) 14 hours prior to euthanasia. Single cell suspensions of mammary tumors were obtained using enzymatic and mechanical dissociation followed by immune cell fraction isolation using gradient centrifugation. Immune cell fractions were sorted by flow cytometry for the isolation of purified CD8α+ T-cells (CD8α-APC, eBiosciences). Sorted CD8+ T-cells were stained for CD3-PE (eBiosciences). Sorted CD8+ T-cells were stained for CD3-PE (eBiosciences) and measured using flow cytometry. Co-staining for EdU incorporation (FITC) and CD8α expression was completed according to manufacturer’s instructions (Life Technologies, Grand Island, NY) and analyzed by flow cytometry. Splenocytes were isolated using mechanical separation of whole spleens followed by elimination of red blood cells using erythrocyte lysis buffer. For proliferation, cells were plated on CD3e antibody coated plates (BD Biosciences) and counted using both manual counting and OD values from crystal violet stained cells. For cytotoxicity assays, splenocyte derived T-cells were co-cultured with R7 mammary tumor cells. After 24 hours, cells were washed to remove T-cells and dead tumor cells, the remaining viable cells were fixed in 4% paraformaldehyde. Following fixation, cells were stained with crystal violet and cell viability read at Abs (570 nm).
Statistical analysis

Statistical analysis for hyperplasia was determined using z-test. Data on tumor development was subjected to Kaplan-Meier analysis using a log-rank test. Incidence data (invasive ductal carcinoma and metastasis incidence) were analyzed using Fisher’s Exact Test. All other data are represented as the mean ± SE and were analyzed with Student’s t-tests using GraphPad Prism software (San Diego, CA). Significance was set at P < 0.05.
