Abstract

The Insider Threat Study, conducted by the U.S. Secret Service and Carnegie Mellon University's Software Engineering Institute CERT Program, analyzed insider cyber crimes across U.S. critical infrastructure sectors. The study indicates that management decisions related to organizational and employee performance sometimes yield unintended consequences magnifying risk of insider attack. Lack of tools for understanding insider threat, analyzing risk mitigation alternatives, and communicating results exacerbates the problem. The goal of Carnegie Mellon University's MERIT (Management and Education of the Risk of Insider Threat) project is to develop such tools. MERIT uses system dynamics to model and analyze insider threats and produce interactive learning environments. These tools can be used by policy makers, security officers, information technology, human resources, and management to understand the problem and assess risk from insiders based on simulations of policies, cultural, technical, and procedural factors. This paper describes the MERIT insider threat model and simulation results.

1 Introduction

Insiders, by virtue of legitimate access to their organizations’ information, systems, and networks, pose a significant risk to employers. Employees experiencing financial problems have found it easy to use the systems they use at work everyday to commit fraud. Other employees, motivated by financial problems, greed, or the wish to impress a new employer, have stolen confidential data, proprietary information, or intellectual property from their employer. Lastly, technical employees, possibly the most dangerous because of their intimate knowledge of an

The Insider Threat Study, conducted by the U.S. Secret Service and Carnegie Mellon University’s Software Engineering Institute CERT Program, analyzed insider cyber crimes across U.S. critical infrastructure sectors. The study indicates that management decisions related to organizational and employee performance sometimes yield unintended consequences magnifying risk of insider attack. Lack of tools for understanding insider threat, analyzing risk mitigation alternatives, and communicating results exacerbates the problem. The goal of Carnegie Mellon University’s MERIT (Management and Education of the Risk of Insider Threat) project is to develop such tools. MERIT uses system dynamics to model and analyze insider threats and produce interactive learning environments. These tools can be used by policy makers, security officers, information technology, human resources, and management to understand the problem and assess risk from insiders based on simulations of policies, cultural, technical, and procedural factors. This paper describes the MERIT insider threat model and simulation results.
organization’s vulnerabilities, have used their technical ability to sabotage their employer’s system or network in revenge for some negative work-related event.

In January 2002 the Carnegie Mellon University Software Engineering Institute’s CERT Program (CERT) and the United States Secret Service (USSS) National Threat Assessment Center (NTAC) started a joint project, the Insider Threat Study. The study combined NTAC’s expertise in behavioral psychology with CERT’s technical security expertise to provide in-depth analysis of approximately 150 insider incidents that occurred in critical infrastructure sectors between 1996 and 2002. Analysis included perusal of case documentation and interview of personnel involved in the incident.

Two reports have been published to date as part of the Insider Threat Study, one analyzing malicious insider incidents in the banking and finance sector (Randazzo et al. 2004), and one analyzing insider attacks across all critical infrastructure sectors where the insider’s intent was to harm the organization, an individual, or the organization’s data, information system, or network (Keeney et al. 2005). Two additional reports will be published in 2006: one specific to the information technology and telecommunications sector, and one for the government sector.

The reports include statistical findings and implications regarding technical details of the incidents; detection and identification of the insiders; nature of harm; as well as insider planning, communication, behavior, and characteristics. The reports have been well-received across several stakeholder domains including the business community, technical experts, and security officers. Our fear is that practitioners will mistakenly interpret the results as stand-alone statistics and assign consideration of individual implications to various departments within the organization instead of taking a holistic, enterprise-wide approach to mitigating insider threat risk.

The results of the Insider Threat Study show that to detect insider threats as early as possible or to prevent them altogether, management, IT, human resources, security officers, and others in the organization must understand the psychological, organizational, and technical aspects of the problem, as well as how they coordinate their actions over time. CERT staff felt strongly that an important next step in our insider threat research was development of innovative communication, education, and training materials to address this issue. After researching potential methods and tools that could be used for this purpose, system dynamics was chosen for its strengths in modeling and simulation of complex problems.

This paper describes the MERIT project. MERIT stands for the Management and Education of the Risk of Insider Threat. The project goal is to develop a system dynamics model that can be used to better communicate the risks of the insider sabotage threat to an organization’s information, systems, or networks. Section 2 motivates the use of modeling and simulation to learn about complex systems, such as the problem of insider sabotage and its mitigation. Section 3 describes in greater detail the Insider Threat Study and related research being conducted by CERT. Section 4 describes a fictional case used as a basis for the MERIT training materials and model development; the case is described more fully in Appendix A. Section 5 describes the primary assumptions and scope of the MERIT model. Sections 6 through 8 describe the behavioral, attack and defense aspects of the model, respectively. Section 9 shows how the model can be used to generate the problematic behavior of the fictional case. Appendix B

contains a comprehensive overview of the MERIT model. Section 10 describes conclusions that can be drawn from the current model, and work that remains to be done. Section 11 contains acknowledgements of researchers and organizations that have contributed to this work. Section 12 contains a list of references.

2 Simulation-Based Learning

Any organization using a computerized network represents a complex system involving both people and technology. Each employee navigates the network with a unique level of access and set of authorized capabilities that may change over time. Each organization exercises a policy to optimize productivity while guaranteeing security, whether or not such a policy is well-developed and implemented. While there are many such systems, and thus a wealth of common experience based on which to learn the important components of a good security policy, it is not a given that all organizations manage this learning well.

Sterman (2006) describes three challenges to implementing good policy based on lessons learned from interactions in complex systems. First, one cannot draw lessons learned unless one has good data. Second, one cannot learn from experience, even with good data, unless one can derive good lessons from that data. Finally, one cannot implement good policy based on lessons learned, unless stakeholders in the system are involved politically in policy development.

Sterman makes compelling arguments that all three of these efforts are hindered by the characteristics of complex systems. Unlike the scientific laboratory, in which variables can be isolated and controlled, the networked organization presents serious challenges to the gathering of valid, reliable, and easily interpretable data from which one can draw clear conclusions. Unambiguous data are difficult to gather because a complex system, such as a networked organization, involves cause and effect interactions across many time scales, locations, and areas of expertise. In addition, complex systems not only respond to the decisions taken by the learner but to decisions taken by other agents in response. Finally, one cannot afford to make risky extreme decisions even though these might yield good data for learning, because of the ethical and logistical implications of experimenting with real organizations. As a result, the specific results of any action taken are difficult to discern.

Even with good data, learning isn’t guaranteed. To derive lessons learned, one would first form hypotheses about system behavior, gather data, and reflect on whether the results matched those predicted. Finally, one would update one’s mental model after reflecting deeply on any discrepancies, in a form of double-loop learning (Argyris & Schon, 1974).

Sterman reviews research from the psychological literature (e.g., Wason, 1966; Kahneman & Tversky, 1982) indicating that people are not normally prone to gather data that might disconfirm their hypotheses, especially not in public (Tedeschi, 1981) or working in groups (Janis & Mann, 1977). When making judgments, we tend to use simplifying rules-of-thumb that may be efficient but are often biased (Kahneman & Tversky, 1982). Finally, not only do we avoid looking where disconfirming evidence might be, we also respond in ways that force the system to exhibit types of behavior that confirm our earlier biased beliefs (Rosenthal & Jacobson, 1968).

Sterman (2006) advocates the use of virtual worlds to overcome our inability to learn in complex systems. These need not be computer simulations, as they can be role-play games or physical model environments as well. In simulations, distinguished from games by their verisimilitude
enabling knowledge transfer beyond the environment (Lane, 1995), it is possible to set up a closed environment with known assumptions. One can then test the impact of policies without the distortion of statistical error and reflect on the outcomes resulting only from one’s own actions.

Lane (1995) reviews the history of such simulations and describes the value of using these to provide managers with an intellectually and emotionally rich and engaging educational experience. Lane points that the low cost and unambiguous feedback afforded can be “more helpful than reality,” as long as certain caveats are considered. The model should represent the relevant environment with fidelity, the simulation instructions should be clear, the simulation objective (such as maximizing productivity and minimizing risk and cost) measurable and known to the user, and there must be an opportunity for debriefing or reflection. In addition, Lane notes that simulations provide common metaphors for communication about insights or lessons learned.

Groessler (2004) elaborates on fifteen issues that should be considered when designing such simulations for training.

- The first five concern the characteristics of the model, and pertaining to how well it balances the fidelity to the context with the necessity for simplification so that lessons can be learned. The model should be validated against real cases without so much complexity as to overwhelm the user.

- The second five address the characteristics of the trainees, balancing the cognitive complexity of the task with the users’ learning styles. The simulation should be part of a larger interactive learning environment allowing individuals many ways to glean insights from using it.

- The third five address whether the interactive learning environment encourages good engagement with the task and reflection on lessons learned. Users of the simulation should have the opportunity to monitor indicators of success and should be given opportunities to reflect on their hypotheses and the results of their experiments.

### 3 Origins of CERT Research

The Security Dynamics Network is a collaborating network of institutions and associated researchers using system dynamics modeling to explore risk dynamics, focusing on cybersecurity. Its members include University at Albany; Agder University College; TECNUN, University of Navarra; Worcester Polytechnic Institute; Sandia National Labs; Argonne National Labs; and Carnegie Mellon University. The network was created in 2004 after members of the group convened several workshops to model various aspects of the insider threat (Melara 2003; Anderson 2004; Rich 2005).

Convinced that system dynamics modeling was a viable mechanism for transitioning our insider threat knowledge, CERT sought funding for development of a prototype interactive learning environment (ILE) based on empirically validated models of the insider threat problem developed using Insider Threat Study data. The purpose of MERIT is to develop an ILE using

---

6 An interactive learning environment (ILE) is a process for educational learning that allows the instructor and student to negotiate the context of the curriculum in the real-time.
system dynamics for hands-on analysis of the effects of policy, technical, and countermeasure decisions on malicious insider activity. It will provide a means to communicate insider threat risks and tradeoffs, benefiting technical and non-technical personnel, from system administrators to corporate CEOs. The MERIT project was funded by CyLab at the Carnegie Mellon University.

At about the same time the MERIT project was initiated, the CERT insider threat team was funded by the U.S. Department of Defense Personnel Security Research Center (PERSEREC) for another system dynamics modeling project. That work is part of an ongoing partnership between CERT and PERSEREC in response to recommendations in the 2000 DoD Insider Threat Mitigation report. The purpose of the PERSEREC/CERT project is to develop two system dynamics models based on actual case data – one for insider IT sabotage and one for espionage – and then compare and contrast the models. The comparison could identify countermeasures that could be useful for mitigating both risk of insider IT sabotage and espionage in the DOD.

CERT researchers believed that the scope of MERIT should initially be limited to a well-defined subset of the 150 cases from the Insider Threat Study. Because a model of insider IT sabotage could be used for both the MERIT and PERSEREC projects, the CERT research team decided to first focus MERIT on insider IT sabotage cases. As a result, a base model is being developed for insider IT sabotage that can be used for both projects.

One unique aspect of the Insider Threat Study that was a key to its success was the equal attention to both the technical and psychological aspects of the problem. MERIT allowed the CERT team to realize unexpected benefits from the overlap with the PERSEREC project. CERT’s technical security expertise was augmented with expertise from several organizations in the areas of psychology, insider threat, espionage, and cyber crime. Therefore, the system dynamics model for insider IT sabotage being developed for both MERIT and PERSEREC benefits from a broad range of experience regarding the technical, psychological, and organizational factors influencing insider threat risk.

3.1 Key Findings from the Insider Threat Study

We base our system dynamics models on findings from the Insider Threat Study, in particular those cases involving insider sabotage. These were among the more technically sophisticated attacks perpetrated in the study and resulted in substantial harm to organizations. In the 49 cases studied, 81 percent of the organizations that were attacked experienced a negative financial impact as a result of insider activities. The losses ranged from a low of $500 to a high of “tens of millions of dollars.” Seventy-five percent of the organizations experienced some impact on their business operations. Twenty-eight percent of the organizations experienced a negative impact to their reputations. The statistics in this section come from the CERT/USSS Insider Threat Study report on insider sabotage (Keeney 2005).

The first step taken in modeling insider IT sabotage was to identify the key findings to be reflected in our system dynamics model. A summary follows:

*Insiders were disgruntled and motivated by revenge for a negative work-related event.* Fifty-seven percent of the insiders who committed IT sabotage were disgruntled. Eighty-four percent

---

7 [www.defenselink.mil/c3i/org/sio/iptreport4_26dbl.doc](http://www.defenselink.mil/c3i/org/sio/iptreport4_26dbl.doc)
were motivated by revenge, and 92% of all of the insiders attacked following a negative work-related event like termination, dispute with a current or former employer, demotion, or transfer.

*Insiders exhibited concerning behavior prior to the attack.* Eighty percent of the insiders exhibited concerning behavior prior to the attack, including tardiness, truancy, arguments with coworkers, and poor job performance.

*Insiders who committed IT sabotage held technical positions.* Eighty-six percent of the insiders held technical positions. Ninety percent of them were granted system administrator or privileged system access when hired by the organization.

*The majority of the insiders attacked following termination.* Fifty-nine percent of the insiders were former employees, 57% did not have authorized system access at the time of the attack, and 64% used remote access. Many used privileged system access to take technical steps to set up the attack before termination. For example, insiders created a backdoor account, installed and ran a password cracker, took advantage of ineffective security controls in termination processes, or exploited gaps in their organization’s access controls.

### 3.2 Targeted Lessons for Training

Based on the above findings, the MERIT team determined that the most important lessons to be conveyed in the interactive learning environment (ILE) are the following:

Disabling access following termination is important; in order to do so effectively organizations must have full awareness of all access paths available to each of their employees. (See Section 5.4 for an explanation of access paths). Since so many acts of insider sabotage were committed following termination, the MERIT ILE must emphasize the importance of completely disabling access upon termination, a task that is often easier said than done. Many of the attacks in the Insider Threat Study were possible because the employer did not know all of the access paths available to their employees.

For example, system administrators created backdoor accounts with system administrator privileges, knowing that because account audits were not conducted the account would not be detected and would facilitate the attack following termination. Other privileged users planted logic bombs - malicious code implanted on a target system and configured to execute at a designated time or on occurrence of a specified system action. Often the insider configured the logic bomb to execute following termination, knowing that no characterization and configuration management procedures were in place to detect the malicious code. Other technical insiders were able to use passwords for shared accounts because there was no formal tracking mechanism for access to those accounts. Therefore they were overlooked upon termination.

The ILE must emphasize the importance of proactive, ongoing, rigorous access management practices to facilitate complete disabling of access upon termination.

---

8 A backdoor account is an unauthorized account created for gaining access to a system or network known only to the person who created it.

9 A password cracker is a program used to identify passwords to a computer or network resource; used to obtain passwords for other employee accounts.

10 Characterization and configuration management refers to procedures and software that track releases and changes to software or system components so that unauthorized access can be prevented or appropriate users alerted when a file has been modified or released.
Management should carefully consider concerning behavior by an employee who appears to be disgruntled following a negative work-related event, possibly increasing monitoring of the employee’s online activity. It is not practical for organizations to monitor all online activity for all employees all of the time. Determining the appropriate balance between proactive system monitoring and other duties of the IT or technical security staff is a difficult task in any organization. However, almost all insiders in the Insider Threat Study sabotage cases exhibited concerning social behavior prior to the attack. Therefore, an important lesson to be conveyed by the MERIT ILE is that organizations should maintain awareness of employee dissatisfaction and evaluate concerning behavior. Targeted monitoring of online activity by employees of concern can prevent insider sabotage by detecting technical precursor activity immediately.

4 Fictional Case for Training: iAssemble, Inc.

As mentioned earlier, an interactive learning environment for training on insider threat is more effective when combined with a concrete case example that clearly illustrates the relationship between aspects of the insider threat and the effectiveness of various measures to counter the threat. However, the sensitivity of actual Insider Threat Study case data precludes the use of actual cases for training. We therefore developed a fictional case scenario that is representative of a preponderance of actual cases of insider sabotage from the Insider Threat Study.

The following characteristics of our fictional case are important:

- Effective access management practices that degrade over time due to competing priorities
- Increased acting out (concerning behavior) by insider
- Increased tension between insider, staff, and managers
- Ineffective management response that would address concerning behavior exhibited by disgruntled employee
- Increased data gathering by insider
- Undetected escalation of access by insider
- False perception by management underestimating insider access
- Punitive actions seem ineffective to management, provocative to insider

The fictional organization is called iAssemble, Inc.11 The full text of the iAssemble case example appears in Appendix A. A summary of the case follows:

iAssemble sold computer systems directly to customers; building each system made-to-order at competitive prices. Ian Archer, the insider threat actor, had been with iAssemble since its founding and was the sole system administrator. The environment at iAssemble was traditionally very relaxed. However, recent substantial company growth resulted in a different culture, as well as new management who hired a new lead system administrator over Archer.

This action triggered Archer’s disgruntlement, feeling his hard work over the years was not appreciated. In addition, the new lead system administrator restricted the privileges of all iAssemble employees, including Archer. Archer vented his anger by openly harassing individuals and purposely stalling progress on important projects. A performance improvement plan was

11 The iAssemble organization and case example are completely fictional, any unintentional resemblance to a real organization or insider threat case is unintentional.
instituted by Archer’s new manager with disciplinary actions including written warnings, a temporary suspension, and reduction in his salary. Suspecting he would soon be fired, Archer created a backdoor with system administrator privileges on iAssemble’s server for later access should his authorized access be disabled or his administrative privileges be revoked.

Management’s increased sense of risk of malicious activity by Archer led them to ramp up audits of access control quality and access management. Unfortunately these measures were put in place too late to prevent or detect Archer’s backdoor installation. When management fired Archer they disabled all known access paths. But unknown to management, a coworker had shared his password with Archer to increase productivity for their project team. Archer used that password to log in remotely to the coworker’s machine the night of his firing. Using the backdoor account he installed a logic bomb on the machinery server, set to detonate three months later.

The logic bomb deleted all the files on the machinery and backup servers leaving the assembly lines at iAssemble frozen. An investigation revealed that access control policies and practices had eroded over time. The investigation lead to the arrest of Ian Archer, but iAssemble was left on shaky ground, causing share prices to plummet. Their image in the market was blemished and stockholders demanded detailed explanations from company management.

iAssemble’s decision to increase monitoring and auditing was the right one - the steps they took increased management’s knowledge of employees’ access paths. However, the gap between management’s knowledge of Archer’s access paths and his actual access was not fully eliminated when he was fired, so iAssemble could not disable all of his access paths in time. Hence, Archer was able take advantage of the residual access that he had to attack following termination.

We believe that the iAssemble case provides a coherent and well-grounded basis for training on the access management issues relevant to insider sabotage and is representative in character (but not necessarily detail) of many of the actual cases that we have seen.

5 Model Assumptions

The following assumptions are key to understanding the dynamics, relationships, and conditions in the MERIT model related to insider IT sabotage and countermeasures.

5.1 Scope

The model begins with the insider at his or her highest position in the organization. Since most insiders became disgruntled and attacked in their current position, they tended not to carry over problems from their previous position. While the time periods related to firing and demotion are important in the model, hiring is not, because significant triggering events related to the attack or prompting the desire to attack did not typically occur soon after being hired. Also within the model scope is a negative work-related event that causes the insider to feel dissatisfied toward the organization, supervisors, or co-workers. Termination or demotion is frequently the last negative work-related event triggering the insider attack.

5.2 Organization

Key to the model is the organization’s knowledge of insider access rights and privileges, rather than the authorization for and legitimacy of insider actions. Most organizations have the ability to track, monitor, and identify access paths for employees, but they can either be unaware of or
forget access paths available to employees due to poor security management practices. In addition, practices such as security awareness and education, account management, and personnel behavioral management, play an important role in the model. Access control is key because insiders require access to perform their job functions but can also use this access to attack. Therefore, imperfect states of practice, particularly with regard to access control, have a heavy influence in the model. Access control may not be perfect at the start of the simulation.

5.3 Insiders
The next group of assumptions deals with the insiders themselves: their means, motives, and opportunities. The model assumes that insiders work alone in attacking the organization and do not collude; this assumption is supported by most of the cases examined in the Insider Threat Study. The method by which the insider attempts to attack the organization is typically limited to the skill sets, experiences, and education exhibited while still an employee with the organization. An insider may attempt or succeed at gaining more access than his organization authorizes, but he will seek to gain this access within the confines of their current skill set, experience, and education.

Insiders tend to feel entitled to perform certain actions or act in a specific way, and this entitlement escalates over time. If they do not receive reprimands, sanctions, or correction, insiders begin to feel that they have the organization’s authorization to behave irregularly. When insiders are penalized or corrected they may react negatively and cause further behavioral disruption or commit technical sabotage.

5.4 Access
Ironically, while access is granted as a necessary course of conducting business operations, it is also one of the most essential elements of insider attacks. Access to information and systems allows employees to read, modify, and delete business and system data. The following section expands on employee access paths, frequently used to conduct attacks.

5.4.1 Access paths
In the MERIT model, access is provided through “access paths”: a set of one or more access points leading to a critical system. Examples of points along access paths are employee badges, computer accounts, passwords, and Virtual Private Networks (VPN). The model presumes that the insider obtains access in one of three ways – access paths are granted by the organization, created by the insider, or discovered by the insider. Access paths can be known or unknown to the organization. An access path that is unknown to management is not necessarily illegitimate, but organizations should reduce unknown access paths by identifying them, reviewing each for validity, and disabling those without a justified business need.

Granted paths are those authorized by the organization. For example, a granted access path for a web server administrator could be software and hardware used to publish corporate web pages. One problem with granted access paths, illustrated in the model, is that organizations can lose track of their existence if formal tracking procedures are not enforced. An example of a forgotten path is a privileged shared account created for a team of software developers for the duration of a project that is not removed or restricted after the project terminates.
Created paths are those established by an employee, such as computer accounts that are created or hacking tools that are installed on the system by the insider. Created paths can be authorized or unauthorized, and the organization may or may not know of their existence.

Discovered paths are existing paths revealed to or discovered by an employee. Although they can be used for malicious insider actions, they may not have been created with malicious intent. An example of a discovered access path is one that is found when an employee learns that he can access information, resources, or network services he did not know existed or for which he did not know he had legitimate access.

Other access path assumptions in the model include:

1. Insiders can lose some or all of their access paths, as well as the ability to create new paths.
2. Insiders who are demoted or terminated may retain the ability to create or use access paths for which they are no longer authorized because of a lapse in procedure or practice.
3. It takes time for organizations to recover from poor access management.
4. Effectively disabling of access paths requires that management have full awareness of all paths available to the employee, and the employee’s ability to create new paths.
5. Even without deliberate action by an insider to obtain a higher level of access, there tends to be a gradual increase in the number of access paths available to an insider over time.

### 5.5 Defenses

The final assumption pertaining to the model deals with organizational defenses and responses to unacceptable employee behavior. Organizations typically use administrative, physical, and technical controls to deter, prevent, detect, and respond to attacks on information and systems, including insider attacks. The MERIT model focuses on administrative and technical controls, since physical controls were not a predominant factor in most cases in the Insider Threat Study.

Administrative and technical controls relevant to mitigating risk of insider threat in the MERIT model are described in Table 1.
<table>
<thead>
<tr>
<th>Policy Lever</th>
<th>Description</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>employee intervention</td>
<td>Positive interventions like employee assistance or counseling that attempt to lower disgruntlement directly, to reduce inappropriate behavioral or technical actions by insider.</td>
<td>May not be effective if quality of intervention is low.</td>
</tr>
<tr>
<td>sanctioning</td>
<td>Punitive measures that attempt to motivate the insider to reduce his inappropriate behavioral or technical actions to avoid additional sanctioning.</td>
<td>May have the opposite effect of increasing disgruntlement and inappropriate actions.</td>
</tr>
<tr>
<td>technical monitoring</td>
<td>Real-time measures to track and analyze an insider’s online actions, such as the use of access paths or information and resources accessed.</td>
<td>If technical monitoring is not initiated or quality is low, management may not have an accurate sense of the risk that an insider poses to the organization.</td>
</tr>
<tr>
<td>training</td>
<td>Currently limited to education of employees on appropriate usage of computer and network systems and the consequences if misused.</td>
<td>Training quality affects the rate of inappropriate online actions and attacks by insiders.</td>
</tr>
<tr>
<td>tracking</td>
<td>Efforts by management to keep track of access paths.</td>
<td>Poor tracking leads to high rates of access paths unknown by management, making it more difficult to disable paths and easier for the insider to conceal his actions.</td>
</tr>
<tr>
<td>auditing and disabling access paths</td>
<td>Efforts by management to discover, understand, review, and disable access paths available to the insider. Allows comparing employees’ abilities and efforts to access information, create access paths, or use access paths against acceptable policies and procedures.</td>
<td>Facilitates discovery of access paths available to the insider. Poor audit allows insiders to amass many unknown access paths making it easier to conceal actions and attack after termination.</td>
</tr>
<tr>
<td>termination threshold</td>
<td>The threshold of risk posed by the insider to the organization above which management fires the insider.</td>
<td>Too high a threshold may give a malicious insider additional time to attack the organization or take technical actions to set up an attack following termination. Too low a threshold may cause the organization to terminate valuable employees who just need a little intervention to solve their problems.</td>
</tr>
<tr>
<td>termination time</td>
<td>The time it takes the organization to terminate an insider once the termination threshold is reached.</td>
<td>If termination time is too long then the insider may maintain authorized access to the system long enough to facilitate an attack.</td>
</tr>
</tbody>
</table>

*Table 1: Simulation Effects of Policy Levers*
6 Modeling Behavioral Aspects

Employee disgruntlement was a recurring factor in the Insider Threat Study sabotage cases, predominately due to some unmet expectation by the insider. For example:

1. The insider expected certain technical freedoms in his\textsuperscript{12} use of the organization’s computer and network systems, such as storing personal MP3 files, but was reprimanded by management for exercising those freedoms.
2. The insider expected to have control over the organization’s computer and network system, but that control was revoked or never initially granted.
3. The insider expected recognition or prestige from management, but was disturbed upon some event in the workplace, such as being passed over for a promotion.

In our model we focus on the first two. Insider freedom thus represents freedom for the insider to use or control the system. Expected freedoms could be measured either by the number or extent of privileges or on a continuous scale from none to root access.

6.1 Insider Expectation of Freedom

Figure 1 depicts changes in the insider’s expectations over time based on his actual freedom as well as the insider’s predisposition to disgruntlement. This predisposition differs from one person to the next, and influences the rate that expectations rise and fall. The rise of expectations is influenced heavily by the actual freedom given insider. As illustrated in reinforcing loop R1, with lax management controls actual freedom grows commensurate with expected freedoms. As more freedom is allowed, more freedom is taken; as more freedom is taken, more is allowed. In the model, it is assumed that even lax management sets an upper bound on the extent of freedoms allowed to any employee.

Lax management unintentionally encourages escalation of expectation. Expectation escalation is seen in the simulation results in Figure 2. The simulation starts off with expected and actual freedom at an equal value of 10 freedom units - the freedom allowed any employee of the organization according to the organization’s appropriate systems usage policy. With lax management, some employees will try to “push the envelope”, using the system regardless of the organization’s usage policy. This is especially true for insiders with a strong sense of entitlement.

As management allows the insider’s actual freedom to increase beyond that permitted by policy, the insider’s expectation also rises. As shown in the figure, expected and actual freedom continue to increase at an equal rate until about week 40, when freedom reaches a point that even lax management will not permit - more than twice the freedom allowed by policy. At this point, the insider expects slightly more than what is permitted; this situation creates an equilibrium condition where unmet expectation stays fairly constant over time.

\textsuperscript{12} Ninety-six percent of the insiders in the Insider Threat Study who committed IT sabotage were male. Therefore, male gender is used to describe the generic insider throughout this paper.
This simulation illustrates a situation in which lax management permits increasing freedom for the insider that can cause major problems later on, especially if that insider has a predisposition for disgruntlement. The trigger for those major problems, which we call the precipitating event, tends to be anything that removes or restricts the freedom to which the insider has become accustomed. In the iAssemble case, as in some of the cases in the Insider Threat Study, the trigger is the hiring of a new supervisor who enforces the organization’s system usage policy.

![Figure 1: Expected freedom by insider](image)

![Figure 2: Expected & Actual Freedom Growth with Lax Supervisor](image)
Figure 3 shows simulation results with a new supervisor hired at week 20 who enforces the usage policy, shown by the drop in actual freedom given insider to 10 freedom units. Coincident with the drop is a commensurate rise in unmet expectation. Expectation rises (about 40% in 20 weeks) much faster than it falls, approaching its original policy level at around week 92, assuming an insider with a strong sense of entitlement. Barring any additional loss of freedom, however, expectations do fall gradually as the insider comes to accept his new situation. Nevertheless, the period of high unmet expectation is one of high risk for the organization as explained below. The additional drop in the actual freedom given insider is also explained below.

Figure 3: Expected & Actual Freedom with Strict Supervisor Hired at Week 20

6.2 Escalation of Disgruntlement and Sanctioning

Figure 4 depicts part of the model, influences of unmet expectation on the insider’s offline behavior and the organization’s response. Three additional stocks are introduced:

- **Insider disgruntlement**: the insider’s internal feelings of discontent due to demands or restrictions by the organization that he perceives as unacceptable or unfair.
- **Behavioral precursors**: observable aspects of the insider’s offline/social behavior inside or outside the workplace that might be deemed inappropriate or disruptive in some way.
- **Sanctions**: the organization’s punitive response to inappropriate behaviors. Sanctions can be technical, like restricting system privileges or right to use the organization’s equipment at home, or non-technical, such as demotion or formal reprimand.

A generic measure, severity units, is used to measure behavioral precursors, damage, and disgruntlement.

---

13 Throughout the paper, “online behavior” refers to actions taken using the computer, while “offline behavior” refers to social behaviors that are not taken on the computer.
Reinforcing loop R2 in Figure 4 characterizes escalation of disgruntlement in response to sanctions for inappropriate social behaviors. As the insider’s unmet expectations increase, Insider disgruntlement increases. Insiders exhibit disgruntlement by acting inappropriately offline. Observable inappropriate offline behaviors vary; some insiders take revenge primarily online, exhibiting fewer offline precursors. We assume that the insider’s predisposition to disgruntlement indicates their tendency to engage in inappropriate offline behavior before an attack.

Continuing around loop R2 of Figure 4, notice that Severity of the actions perceived by org is impacted by time to realize insider responsible. Severity of actions influences the extent of sanctioning, which further limits the actual freedom given insider. These dynamics explain the second decrease in actual freedom in Figure 3 at around week 24, after the new supervisor imposes sanctions further limiting the insider’s freedom. The model in Appendix B also shows that technical restrictions on the insider can further limit the insider’s actual freedom.

Instead of (or in addition to) punitive measures, organizations may take positive actions to address an insider’s disgruntlement. Such actions, represented as employee intervention, include referral to an employee assistance program or counseling. Balancing loop B2 in Figure 4 reflects use of employee intervention to address disgruntlement. The organization’s perception of the severity of the Behavioral precursors, the observable manifestation of the insider’s disgruntlement, and organizational policies determine whether positive intervention or sanctions are warranted.

---

Figure 4: Escalation of Disgruntlement and Sanctioning

14 Severity of actions perceived by org is a smooth of several factors and may also be considered a stock.
Figure 5 shows the increase of Insider disgruntlement due to the insider’s unmet expectation that arises due to the new supervisor’s strict enforcement of the organization’s usage policy. With only minimal employee intervention (0.2 on a scale from 0 to 1), disgruntlement rises to almost three times its normal level at about week 24. The predisposed insider begins to act out offline and receives two sanctions during this time period.

![Graph showing the increase of Insider disgruntlement and sanctions]

**Figure 5: Escalation of Disgruntlement and Sanctioning with Minimal Intervention**

Figure 6 provides a notional view of how proactive employee intervention can decrease both disgruntlement and the sanctions needed to address inappropriate behavior arising from that disgruntlement. In this case, even the predisposed insider is much less disgruntled and warrants less of a punitive response, i.e. only one sanction. One nice aspect of employee intervention is that by treating disgruntlement directly, there is less need for punishment and corresponding less disgruntlement caused by the punishment. Thus, when intervention works it is a win-win situation for both the organization and its employees. We are still investigating the general characteristics of the insider and the intervention itself that underlie the success of the approach.

7 Modeling Technical Attack Aspects

As previously mentioned, an organization’s full awareness of access paths available to an insider is critical to being able to disable those access paths when needed. Two stocks model this dependency: Insider access paths unknown to org and Insider access paths known to org.

Figure 7 shows the flows between these two stocks:

- **forgetting paths** flow: Management or the IT staff may forget about known paths, making them unknown. For example, a manager might authorize a software developer’s request for the system administrator password during a time of heavy development, but if a formal list of employees with access to that password is not maintained then the manager could forget that decision over time, or the manager could leave the organization, leaving no “organizational memory” of the decision.
• *discovering paths* flow: Management or the IT staff can discover unknown paths, making them known. Discovery can be accomplished by auditing, for example, when new accounts could be discovered with system administrator or privileged access that were previously unknown to management.

Insiders can acquire new paths unknown to the organization via the *acquiring unknown paths* flow. Finally, organizations can disable known paths via the *disabling known paths* flow. This stock and flow structure is used in the refinement of the technical aspects of the model described in the section below.

![Figure 6: Disgruntlement and Sanctioning with Proactive Intervention](image)

![Figure 7: Access Path Stocks and Flows](image)

### 7.1 Attack Setup and Concealment

As discussed earlier, an insider’s *predisposition to disgruntlement* and unmet expectations can lead to increasing disgruntlement which, if left unchecked, can spur not just behavioral precursors but technical disruptions and attacks on the organization’s computer and network systems. Prior to the actual attack, there are typically *Technical precursors* - actions by the insider to either set up the attack (for example, installation of a logic bomb) or to put in place mechanisms to facilitate a future attack (for example, creation of backdoor accounts to be used later for the attack). These online *Technical precursors* could serve as an indicator of a pending attack if detected by the organization. Figure 8 depicts the influence that insider disgruntlement...
can have on the occurrence of *Technical precursors* that could indicate a pending attack. The figure shows that both unknown and known access paths can be used to set the stage for attack.

**Figure 8: Attack Setup and Concealment**

The extent to which insiders rely on unknown access paths depends on their *desire to conceal actions*. Insiders who do not care whether they are caught, or insiders acting impulsively (often out of the passion of the moment), may use both known and unknown paths in their attack. Insiders who are particularly risk averse may only attack using access paths that are unknown to the organization. Of course, an insider may not know whether the organization is aware of a particular access path or not. Nevertheless, in either case, insiders generate *Technical precursors* that suggest suspicious activity. To perceive the severity of these precursors, the organization must have a *technical monitoring quality* sufficient to detect the precursors in the first place.

### 7.2 Attack Escalation

As shown in Figure 9, *Insider disgruntlement* contributes directly to the rate of inappropriate technical actions taken by the insider, especially actions that facilitate the attack. Some of these actions also contribute to the damage potential of the attack. Examples include sabotage of backups and decreases in the redundancy of critical services or software.

Since insiders in most sabotage cases studied were motivated by revenge, the model assumes that the actual attack occurs once the damage potential reaches an *attack threshold* defined by the insider, provided that the disgruntlement level is sufficiently high. Multiple attacks may be executed provided that a sufficient number of access paths are available to set up and execute the subsequent attacks. If the attack execution is autonomous (for example a logic bomb set to go off when the system reaches a certain state) the insider may need no access paths to the organization’s critical systems in order to execute the attack. In such a case, the planting of the logic bomb could actually be considered to be the attack.

Figure 10 shows the simulation results with *predisposition for technical sabotage* and *insider desire to conceal actions* set to 1. *Insider disgruntlement* rises to its highest level at about week 35 after which the attack is executed. At week 20, prior to the attack, *Behavioral precursors* are the first observables indicating the insider’s disgruntlement. About 4 weeks later the *Technical precursors* start to appear. We believe that this pattern of behavioral disruption before technical disruption is common among many insiders.

Some insiders install unauthorized tools for non-malicious purposes immediately after they are hired. For example, one system administrator installed a root kit - a “hacker” tool used to maintain access to a system without the owner’s knowledge. These tools provide insiders with unauthorized access that makes their work more convenient. These actions are technical
precursors that increase risk of an attack if that insider ever becomes angry enough to take revenge on his employer.

The severity of the technical precursors rises above the severity of the behavioral precursors at about the time of the attack. *Attack damage*, which for obvious reasons has severity much higher than the behavior or technical precursors, occurs immediately at the time of the attack. Technical precursors level off immediately after the attacks because disgruntlement is greatly reduced by attack execution. We are still investigating the exact relationship between attack execution and insider disgruntlement, but we believe that the behavior exhibited by the current model to be representative of the insider sabotage cases in our study.

![Figure 9: Attack Escalation](image)

![Figure 10: Attack Simulation](image)
8 Modeling Technical Defense Aspects

In the fictional case, iAssemble’s defenses against insider attack were purely reactive, based on severity of insider actions and risk subsequently perceived. Figure 11 depicts two defensive actions:

- **Auditing the organization’s systems to discover unknown access paths available to the insider** - Auditing must be followed by disabling those paths (loop B3) for this defense to have significant effect. It is possible, however, that an organization’s discovery of access paths would be a sufficient deterrent for a risk-averse insider if the insider knows the organization has discovered the paths.

- **Reducing the insider’s access path creation ability (loop B4)** - This defense reduces the insider’s ability to acquire new unknown paths.

Both of these defenses target access paths that may be used by the insider to set up or execute an attack. A risk-averse insider, who will not attack unless he can conceal his actions, will have less incentive to attack if unknown access paths are disabled. Known access paths can also be disabled if they are not needed by the insider to perform critical job functions.

If an organization disables the access paths required to fulfill the insider’s job responsibilities, his performance and the organizational mission may be negatively impacted. However, if the perceived risk is sufficiently high, the organization may choose to disable the insider’s access paths anyway. Within the simulation run, if the risk reaches a termination threshold, the insider is fired and all known access paths are immediately disabled. Of course, any unknown access paths still available to the insider may be used to set up and execute an attack.

*Figure 11: Risk-based Auditing and Access Path Disabling*
Figure 12 shows the results of executing the model with audit quality set at 50%, the same level of audit used to generate the results for Figure 10. In Figure 12, however, the number of access paths available to the insider is shown, both known and unknown to the organization, over time. The insider is terminated at about week 32; all known access paths are disabled at time of termination. However, with audit quality at 50%, the insider still has enough unknown access paths to continue to set up and execute the attack at about week 38.

To test the effects of auditing, Figure 13 shows the results using the same parameter settings except that audit quality is set to 80%. Here, the higher level of audit quality keeps the number of access paths unknown to the organization sufficiently low so that no attack can be executed, before or after termination. The Technical precursors suggest that the insider started to set up the attack, but the organization’s defenses were sufficient to stop the insider before he reached the attack threshold. For an attack threshold of severity 2, the tipping point for the attack is an audit quality of between 68% and 69%. Future work will determine what it means for an audit process to be of a certain quality. Of particular interest will be the characteristics of an audit at the tipping point for an attack.
9 Exhibiting the iAssemble Reference Mode

This section demonstrates that the MERIT model exhibits the behavior of the iAssemble case. Since the iAssemble case is representative of a preponderance of sabotage cases analyzed in the Insider Threat Study, we believe this model represents key issues in insider IT sabotage cases. From this we infer that the model is useful for identifying and analyzing the solution space, which includes policy, procedural, and technical measures that, when used together, can significantly help prevent or detect insider IT sabotage.

Figure 14 shows the increasing gap between the perception of the insider’s access paths and the actual access paths available to him, which has the same general pattern as in the iAssemble case of Figure 19.
This perception gap indicates an erosion of the organization’s control of access to its systems. 

Access control quality (ACQ) is defined as follows:

\[
\text{access control quality} = w_u \times \text{unknown path access control quality}
+ w_k \times \text{known path access control quality}
\]

where

- \( w_u \) is the weight that the organization gives to unknown access paths to determine the access control quality
- \( w_k \) is the weight that the organization gives to known access paths to determine the access control quality and is equal to \((1 - w_u)\)

So access control quality is perfect if and only if unknown path access control quality is perfect and known path access control quality is perfect.

We further define

unknown path access control quality

\[
= \text{effect of access paths on ACQ} \left( \frac{\text{Insider access paths unknown to org}}{\text{max reasonable paths}} \right)
\]

known path access control quality

\[
= \text{effect of access paths on ACQ} \left( \frac{\text{extraneous access paths known to org}}{\text{max reasonable paths}} \right)
\]
where

- **max reasonable paths** is the number of access paths, known or unknown, beyond which no additional benefit is gained by the insider.
- **paths insider needs to do job** is the minimum number of access paths the insider needs to fulfill his job responsibilities.

The function **effect of access paths on ACQ**, shown in Figure 15,

![Graph Lookup - effect of access paths on ACQ](image)

*Figure 15: Function Defining Effect of Access Paths on Access Control Quality*

The above assumes that an organization has perfect control of an employees’ access if the following conditions hold:

1. The employees have no access paths unknown to the organization.
2. The employees have access only to access paths needed to do the job.

Employees with access to paths not meeting one of those two conditions indicate an access control lapse. The model’s access control metric weighs access control lapses in condition 1 more heavily than those in condition 2. The graph of access control over time is shown in Figure 16. This figure has the same general shape as given in the explanation for the iAssemble attack given in Figure 18. The rate of acting inappropriately online roughly captures the sharing of passwords and the installation of a backdoor prior to the termination and the unauthorized access and planting of the logic bomb during and after termination.
10 Conclusion

The MERIT project was initiated as a proof of concept – to determine whether or not an effective interactive learning environment could be developed to teach executives, managers, technical staff, human resources, and security officers the complex dynamics of the insider threat problem. An appropriate ILE must be intuitive enough to be easily understood by practitioners who have most likely never heard of system dynamics.

The steps required to develop the ILE are:

- Gather and analyze extensive insider threat cases (completed - Insider Threat Study)
- Scope the problem for the model (completed - IT sabotage cases)
- Put together team of experts (completed – team consists of experts in insider threat, system dynamics, technical security, psychology)
- Build the model (in progress – current model described in this paper)
- Run simulations for initial testing and calibration of the model (in progress – some simulations described in this paper)
- Create training materials to accompany the model and ILE (student led development of training materials document as part of student project report (Desai 2006))

At this point, the MERIT team feels confident that an effective model that conveys important lessons regarding insider threat has been created. The simulations accurately mimic the patterns and trends in the majority of the cases in the Insider Threat Study. Further calibration and validation of the model is still necessary before it can be released for educational or training use. In addition, extensive user interface testing will be required to develop an intuitive interface and accompanying training materials before it can be used in an actual training class.
In addition to training, the MERI T team plans to present the model to experts in technical security, human resources, and organizational dynamics to calibrate it accurately so that it can be used for additional insights into the insider threat problem and effective countermeasures.

Appendix A: The iAssemble Training Case

iAssemble sells computer systems directly to customers, building each system made-to-order and offering competitive prices. iAssemble has been doing extremely well and conducted an initial public offering (IPO) in 2001, after which its stock doubled.

Organization Background

iAssemble is headed by Chris Eagles, who is the Chief Executive Officer (CEO). Eagles started the company in 1997 with two of his friends, Carl Freeman and Caroline Thompson, who are now the Chief Financial Officer (CFO) and Chief Technical Officer (CTO), respectively. The company had continually hired experienced managers and employees over time.

Ian Archer, the malicious insider, was among the few employees who had been with iAssemble since its establishment. Archer started out as computer specialist and technical assistant to the three original founders, Eagles, Freeman, and Thompson. When hired, Archer held certifications in personal computer (PC) hardware maintenance and operating system administration but did not possess a four-year, baccalaureate degree. He compensated for his lack of education with hard work and over the next four years he became the sole system administrator at iAssemble.

iAssemble grew at a moderate rate. Recognizing the need for qualified personnel, Eagles and Thompson began to hire experienced system administrators who could also function as project managers. Lance Anderson was hired as lead system administrator because of his education and qualifications, and, James Allen was hired as a Junior System Administrator to share Archer’s growing systems administration workload and responsibilities.

Insider Situation

Ian Archer had always been responsible for the software that ran the assembly machinery, and played an important role when iAssemble automated its PC assembly processes.

Archer’s disgruntlement grew steadily over the course of several months due to the growth and associated changes at iAssemble. When Anderson was handpicked for the Lead Administrator position by Caroline Thompson, Archer began to feel confined in his current role and saw limited opportunities for advancement. Policy changes by Anderson meant that Archer could no longer work with the freedom he had always enjoyed. He began receiving detailed instructions on how to work and felt “micro-managed.” Archer’s performance slumped, prompting Anderson and senior management to look to others, such as Allen, for important projects. As a result, Archer felt detached from the new culture at iAssemble, its leadership, and its continuing success.

Archer was assigned to mentor Allen and ensure his smooth assimilation within iAssemble’s culture. Archer and Allen worked on a few small projects together but Archer felt that the projects were too menial for his technical skills. He found Allen to be nearly as technically competent as himself, which contributed to his frustration. While working on one of these projects, Allen shared the password to his personal desktop machine at iAssemble, named

---

15 The iAssemble organization and case example are completely fictional, any unintentional resemblance to a real organization or insider threat case is unintentional.
sharing the password enabled each of them to access the project files when the other was out of the office.

Archer’s disgruntlement grew, and he openly proclaimed that Anderson, was just a namesake. If anyone disagreed he verbally abused them until they backed down and apologized. He even bottlenecked projects on purpose on several occasions, stalling his work on the project to ensure Anderson and the project team missed project milestones. Archer received a written warning from Thompson after several co-workers formally complained. Enraged by this, he had a heated argument with a team member who then quit the very next day, citing Archer as the reason for his resignation. Archer was suspended for a day without pay and received a cut in his salary.

At this point Thompson became more cautious regarding Archer and wanted to fire him. Anderson warned that firing a disgruntled system administrator was a complicated task. Almost every company he worked for had access control gaps that would allow an ill-tempered ex-employee to cause system damage. He suspected such a scenario existed for iAssemble, and in the face of Archer’s firing, could be risky. Anderson believed that yearly audits iAssemble conducted lacked proper vigor and documentation, and there was no way to be certain that they had reduced their risk to sabotage by a former employee. A decision was made to increase audits of access control quality and access management. The audits would begin immediately.

**Insider Attack**

After the blowup with his team member and the subsequent salary cut, Archer had the feeling that he would soon be fired. He decided that he needed to have the means to get back at iAssemble in the event that his worst fears came true.

The audits revealed a great deal about iAssemble’s access management. Many access paths, both of present and past employees, were discovered which should have been disabled. Dummy accounts were discovered which were created for testing and debugging purposes but never deleted; a few had even been created by Archer. These access paths were promptly disabled. Thompson felt there was steady progress being made and deemed the audit an excellent decision.

In the meantime, Archer planted a backdoor on the main machinery server that provided him with unauthorized access. Archer’s immediate anger with iAssemble was alleviated a little after this act, but he was still disgruntled.

Archer became infuriated when he overheard that management was planning to fire him. He decided to wait until after his termination, then seek revenge. Two days later, on December 14, 2001, Archer was fired and his access disabled. Unfortunately, iAssemble managers were not aware that he knew the password to *Kilimanjaro*, James Allen’s iAssemble machine, and did not think to change it. Archer went home the night he was fired and successfully logged into *Kilimanjaro*. He then used his backdoor on the machinery server to plant the logic bomb. He did the same on both of the backup servers. He cleverly set it to go off two months from that date to deflect suspicion from him. Figure 17, below, shows Ian Archer’s attack method.

On February 14, 2002, the logic bomb went off, deleting all files on the machinery server and its backup servers, leaving the assembly lines at iAssemble frozen.
Organization’s Response

When investigators suggested the possibility of insider attack, management was puzzled as to how that was possible in light of the increased monitoring, policies and best practices in place at iAssemble. Eventually, the system logs were used to trace the access to the machinery server from Kilimanjaro. James Allen claimed that he was innocent and explained that he had given the password to his machine to Archer when they worked together.

Ian Archer was soon arrested, but iAssemble was left on shaky ground. Their share prices plummeted and their image in the market was blemished.

Management concluded that growth took its toll at iAssemble with the company facing access control and employee disgruntlement issues. With a whopping growth in sales figures of 68% over the past quarter, iAssemble was rapidly hiring good and efficient people. However, this situation created competition for positions within iAssemble, leading to job dissatisfaction among some employees. Access control quality also eroded over time with employees under pressure to meet deadlines and subsequently violating security policies. Figure 18 depicts the dynamics that occurred at iAssemble.

Figure 17: Insider’s Method of Attack
Despite iAssemble’s efforts to maintain information security best practices, security policy enforcement became lax in support of the culture of growth at all costs. Hence, access control deteriorated over time.

When iAssemble management realized that they needed to increase monitoring and audits, they started out on the right foot. The steps they took ensured that management’s knowledge of their employees’ access paths increased. However, the skew between management’s knowledge of Archer’s access paths and the actual access paths that Archer had, was not fully overcome by the time Archer was fired, and iAssemble could not disable all of his access paths in time. Hence, Archer was able take advantage of the residual access that he had, as shown in Figure 19.
Figure 19: Analysis of Insider Access Level
