SUMMARY

Following a suggestion of Dr. C. A. Thomas and with the cooperation of the General Motors Research Laboratory, a condenser type gage developed for use as a gas engine indicator has been applied as a reliable and relatively simple device for studying the pressure and thrust characteristics of jet propulsion motors. The equipment is in regular use at the composite propellant pilot plant of the Monsanto Chemical Company at Dayton, Ohio.
This report describes the pressure and thrust measuring apparatus which has been installed at the pilot plant of the Monsanto Chemical Company in Dayton, Ohio.

Principle of Operation

The principle of operation is shown schematically in Figure 1. The pressure to be measured is applied to a condenser type gage developed by the Physics Instrumentation Division of the General Motors Research Laboratories in Detroit. (E. J. Martin, G. E. Grinstead and R. G. Prawley, "An Electrical Engine Indicator for Measuring Static and Dynamic Pressures", Trans. A.I. E.E., March, 1941.)

The pressure causes a change in the electrical capacity of the gage which affects the frequency response of a tuned radio frequency transformer thereby changing the output of the transformer. The output of the transformer is detected and lead to a bucking circuit which acts as a gain control and zero adjustor. The output from the bucking box is applied to an oscillograph and the deflection of the oscillograph beam is recorded by a synchronously driven continuous film movie camera. For measuring thrust, the reaction force is applied to a piston acting in an oil filled cylinder. The pressure developed in the cylinder is then measured with the condenser gage.

The oscillograph, camera and control panel are shown in Figure 2.

Description of the Apparatus

1) Condenser Gauges

Gages with 1000 and 3000 pounds per sq. in. pressure range have been obtained from the General Motors Research Laboratories. These gages are shown in Figure 3 and a representative diagram of their construction is given in Figure 1. The two tubes on the 3000 pound gage are water connections for temperature control but this feature has not been used. The water cooled gage was designed primarily for use in cylinders of internal combustion motors where extreme temperature changes would take place. The operation of the gage depends on the change in capacity produced by the deflection of the bottom diaphragm with respect to the inner central electrode. The gages are small, very rugged and may be obtained in any range up to 10,000 lbs. per sq. in.
Gage Adapter Couplings

Since the tension on the gage body threads can affect the spacing of the plates of the condenser, it was found advisable to insert the gage into a permanent adapter coupling in order to have constancy of measurement together with interchangeability of gages. This coupling is constructed so that the gage seats on the inner shoulder and is gasketed with a copper washer to prevent pressure getting up into the threads. The adapter fits directly into the thrust cylinder. In order to use the gage for pressure measurements in the motor, a second adapter is used. This adapter has a 3/8" pipe thread to fit the standard 3/8" tapped holes for gage gages. To protect the gage from the hot gaseous, the adapter is filled with vaseline and plugged with modeling clay. Diagrams of the adapters are shown in Figure 4 a, b.

Thrust Cylinder

The thrust cylinder is shown in Figure 5. The piston has an area of one square inch and the cylinder and piston are honed to a 0.0005" fit. The back of the cylinder has three threaded openings, one for the gage, one for a blow out safety valve and one for filling with oil and removal of air bubbles. S.A.E. 30 oil is used.

Safety Valve

Because of the limited space between the diaphragm and the central electrode (0.0008"), it is necessary to protect the gage from overload in those cases in which excessive thrusts are produced by slowing out of the orifice plate. For this purpose the diaphragm valve shown in Figure 4 c is inserted in the oil cylinder. Suitable blow out pressures can be obtained by using various thicknesses of shim brass or steel for the diaphragm.

Power supply, Oscillator-Detector and Bucking Box

The power supply, oscillator-detector and bucking box were obtained from the General Motors Research Laboratories and are described in Trans. A.I.E.E. March, 1941.

The power supply is a regulated D.C. voltage source which can be varied from 200 to 500 volts. The normal operating voltage is around 250 volts. The power supply furnishes the necessary steady voltage to operate the oscillator in the oscillator-detector unit. It also furnishes the filament voltage for the tubes in the oscillator-detector.
The oscillator-detector unit contains a radio frequency oscillator, a tuned radio frequency transformer and a diode detector. In order to increase the stability to mechanical shock, the 140 μf midget tuning condenser was replaced with a 35 μf double spaced midget tuning condenser and fixed condensers. The 35 μf tuning condenser gives sufficient range to cover most of the resonance curve and is free from mechanical vibration effects.

The bucking box consists of a 10 tap 600,000 ohm resistor, a potentiometer and a 90 volt battery. The output voltage from the detector is applied across the tapped resistor which is then used as a gain control. The tapped-off voltage is bucked by the battery and potentiometer so that the output to the oscillograph is zero volts when no pressure is on the edge.

6) Oscillograph

The oscillograph is a standard Du Mont type 508 with a 5" blue phosphor short persistence screen. The oscillograph is modified, as described in the Du Mont instruction manual, so that the input goes to the D.C. portion of the vertical amplifier and the connections to the vertical and horizontal deflection plates are interchanged so that the deflections on the screen can be photographed with a camera having vertical film motion. A further modification is made to bring out a separate external beam switch which can be synchronized with the firing to prevent excessive burning of the screen by the high intensity spot.

7) Camera

The camera used is a Burke and James Universal 35 mm. movie camera. The camera is modified for continuous film movement by removing the shutter, claw movement and fade out mechanism. The film sprocket wheel is driven by an 1800 R.P.M. synchronous motor coupled through spur gears to a Boston gear reducer. No trouble has been experienced due to delay in reaching synchronous speed. Various film speeds from 0.75 to 6 inches per second can be obtained with proper choice of gear box and spur gears. Since most tests are of 0.5 second duration, a film speed of 3 inches per second has been used. A 4-1/4" focal length lens with f/4.5 aperture was adapted to the camera in order to get full film coverage with a minimum of error due to screen curvature. Eastman Type 1001 Release Positive film is used. This film has a very clear base, excellent contrast and good sensitivity in the blue.

8) Timer

Time mark is placed on the film by photographing the flashes
from a R.C.A. Type 901 glow discharge tube. The tube is operated with half wave rectified 60 cycle voltage giving 60 flashes per second. The light from the tube is brought into the angle of view of the camera by means of a mirror. Although time marks are put on all the records, the time of burning is calculated from the linear film speed. The time marks are used only to check irregularities.

9) Ignition Timer

In order to get a measure of ignition delay, a short duration pulse is put on the base line trace at the instant the firing switch is closed. The pulse is applied by charging a condenser through a low resistance inserted at the grounded end of the bucking box gain control. The voltage developed across the resistance appears as a pulse of a few milliseconds duration. The firing circuit and the pulse circuit are synchronized by using a double pole relay to close the two circuits.

10) Shot Numberer

An identification number is placed on each record by reflecting a set of illuminated stenciled numbers into the view of the camera.

11) Control Switch

A multiple switch was constructed to control the sequence of operations involved in the firing of a shot. The switch consists of a box containing six roller leaf micro switches actuated by a sliding contact plate. The contact plate has adjustable cams for obtaining the desired sequence of switching. At present the sequence is as follows: numberer light on, numberer light off, oscilloscope beam on, timer on and firing circuit on.

12) Motor Support

The mounted motor is shown in Figure 6. The motor rests on two V supports made of angle iron and is held in place with yokes made of roller chain. For thrust measurements the front of the motor rests against the piston of the thrust cylinder which is bolted to the back plate of the bomb shelter.

Operation of the Apparatus

In adjusting the apparatus, the tuning condenser of the oscillator-detector unit is set for maximum output as read on the milliammeter. The power supply voltage is then adjusted.
so that the maximum output is 1.00 ma. The capacity of the
tuning condenser is then increased until the reading is
0.82 ma. This tunes the transformer to the portion of the
resonance curve near the point of inflection and gives the
position of maximum sensitivity to capacity changes. The
position of maximum sensitivity to capacity changes is then set to the desired gain and
bucking box gain control is then set to the oscillograph beam to
the potentiometer adjusted to bring the oscillograph beam to
the zero position. All other operations are then performed
by throwing the multiple switch.

Figure 6 shows some representative pressure and thrust curves;
c) and d) are pressure records and a) and b) are thrust records. The
oscillations at the beginning of the thrust records are
probably due to the high inertia of the motor, impact phenomena
due to imperfect contact of motor and piston and residual air
bubbles in the hydraulic system.

**Calibration**

The gage is calibrated against a calibrated Bourdon test gage
using an oil pressure system and a Blackhawk hand pump. Figure 8
shows the output voltage, as measured from the bucking box with
a vacuum tube voltmeter, as a function of pressure. Since the
gain control is turned down, the actual output from the
oscillator-detector is five times the plotted values. The
maximum sensitivity is therefore 3.20 volts per 1000 pounds per
sq. in.

Figure 9 shows the voltage sensitivity of the D.C. channel of
the oscillograph as recorded with the camera. Figure 10 shows
the calibration curve of the gage as recorded by the camera.
The observed sensitivity of the gage is 212 pounds per square
inch per millimeter deflection on the film. The sensitivity
as calculated from Figures 8 and 9 is 208 pounds per square
inch per Allimeter deflection.

Despite the excellent calibration shown in Figures 8, 9,
and 10, we have experienced some difficulties in obtaining
reliable calibration values. In particular there have been
sinusoidal changes in the calibration value and gradual changes
with change in temperature. The first difficulty is attributed to the use of beaded coaxial cable to connect the gage to the
oscillator-detector unit. This type of cable has unsatisfactory
mechanical stability and is subject to humidity and temperature
effects. A new type solid dielectric coaxial cable is being
tested. The second difficulty obtained to replace the beaded cable. The second difficulty
appears to be due to the use of ordinary steel for the gage
adaptors. Many of the gage are made of low expansion coefficients
of the invar steel and the differential expansion of the two materials
invar steel and the differential expansion of the two materials
invar and steel are being obtained.
CALIBRATION OF D.C. CHANNEL OF
DUMONT TYPE 268 OSCILLOGRAPH

SENSITIVITY = 25 MM/VOLT

FIGURE 9
Pressure to be measured is applied to condenser type gage. Pressure causes change in electrical capacity of gage which affects frequency response of tuned radio frequency transformer thereby changing output of transformer. This is detected and leads to bucking circuit which acts as gain control and zero adjuster. Output from bucking box is applied to oscillograph, and deflection of oscillograph beam is photographically recorded. For measuring thrust, reaction force is applied to piston acting in oil-filled cylinder.
