NEURAL NETWORK HURRICANE TRACKER

STATEMENT OF GOVERNMENT INTEREST

The invention described herein may be manufactured and used by or for the Government of the United States of America for governmental purposes without the payment of any royalties thereon or therefor.

BACKGROUND OF THE INVENTION

(1) Field of the Invention

The present invention relates to a method for predicting the path of a hurricane and to a system for implementing the method.

(2) Description of the Prior Art

Neural networks are well known in the prior art. U.S. Patent Nos. 5,461,699 to Arbabi et al. and 5,563,983 to Nozaki et al. illustrate some of the prior art layered neural network systems. Arbabi et al. describe the use of such a neural network in a forecasting system.

Attempts have been made to develop systems using neural network technology for predicting weather related and natural phenomena. U.S. Patent No. 5,140,523 to Frankel et al. describes a neural network for predicting lightning. U.S. Patent No. 5,490,062 to Leach et al. describes a neural network earthquake profile predictor. There have been no known efforts to date to

19980825 126

1 use neural network technology in a method or a system for
2 predicting the path of a hurricane.

3 Currently, satellites are used to obtain the data needed to
4 track a hurricane. Data generated by the satellites is used to
5 create physical models for forecasting purposes. Statistically
6 based techniques are used to generate the forecasts. Several
7 problems exists with this approach. First, initial information
8 provided by the remote sensors on the satellites is sparse,
9 making the prediction process more formidable in the early stages
10 of the hurricane's formation and movement. Second, the measured
11 parameters like wind speed and location have a great deal of
12 uncertainty. Third, forecasting has a subjective component
13 making the requirement for skill and experience a necessity.

14 The hurricane path prediction method and system of the
15 present invention overcome these shortcomings in the existing
16 hurricane prediction systems.

17

18

SUMMARY OF THE INVENTION

19 Accordingly, it is an object of the present invention to
20 provide a neural network based system for predicting the path of
21 a hurricane.

22 It is a further object of the present invention to provide a
23 system as above which has an inherent capability to incorporate
24 historical data in the prediction process.

1 It is yet a further object of the present invention to
2 provide an improved method for predicting the path of a
3 hurricane.

4 The foregoing objects are realized by the system and method
5 of the present invention.

6 In accordance with the present invention, a method for
7 predicting the path of a hurricane broadly comprises providing a
8 neural network having a plurality of layers including an input
9 layer, an output layer, and an intermediate or hidden layer
10 between said input and output layers, inputting real-time
11 information about a hurricane being tracked into the input layer,
12 and outputting an output signal from the output layer
13 representative of a predicted path of the hurricane being
14 tracked.

15 The system for implementing the above method broadly
16 comprises means for gathering real-time data about said hurricane
17 and a neural network having an input layer for receiving the
18 real-time data about the hurricane, an intermediate or hidden
19 layer for processing the data, and an output layer for generating
20 a signal representative of a predicted path for the hurricane.

21 Other details of the method and system of the present
22 invention, as well as other objects and advantages attendant
23 thereto, are set forth in the following detailed description and
24 drawings.

1 sensors provide information or data about the hurricane. The
2 data may include the location of the hurricane center in latitude
3 and longitude (degrees), the pressure in the hurricane center in
4 inches of pressure, the velocity of the hurricane center in knots
5 or kilometers/hour, hurricane wind direction (degrees), and the
6 maximum wind speed of the hurricane in miles/hour. The module 12
7 is preferably formed by a portion of a preprogrammed computer and
8 preferably includes computational devices for determining or
9 computing certain input parameters such as changes in the
10 velocity of the hurricane center and average wind speed of the
11 hurricane and for scaling data prior to input to neural network
12 14 and means for storing the data. The computational devices
13 (not shown) may comprise any suitable devices known in the art.
14 For example, they can be a portion of the computer programmed to
15 carry out certain computational functions. The data supplied
16 from the module 12 to the neural network 14 is termed real-time
17 data since it is based on information received from the remote
18 sensors. The data supplied by the module 12 to the neural
19 network 14 is preferably updated at predetermined intervals, for
20 example every two hours. The data may also be fed from the
21 module 12 to the database 18 for long-term storage.

22 FIGS. 2(a)-2(f) illustrate some of the information which may
23 be supplied by the module 12 to the neural network 14 and used to
24 generate a prediction of the hurricane track. FIG. 2(a) is
25 information about the location history of the hurricane center in
26 terms of longitude and latitude. FIG. 2(b) is information about

1 the velocity of the hurricane in knots as a function of time.
2 FIG. 2(c) is information about the change in the velocity of the
3 hurricane in knots per hour as a function of time. FIG. 2(d) is
4 information about wind speed in miles per hour as a function of
5 time. FIG. 2(e) is information about the pressure in the center
6 of the hurricane in inches as a function of time. FIG. 2(f) is
7 information about the wind direction in degrees. The data
8 supplied to the neural network 14 may actually be estimates of
9 the aforementioned data measurements.

10 Referring now to FIG. 3, the neural network 14 comprises an
11 input layer 20, an intermediate or hidden layer 22 and an output
12 layer 24. The input layer 20 comprises a plurality of neurons 26
13 with at least one input neuron for each input data set. For
14 example, where the input data to be supplied to the neural
15 network is the information shown in FIGS. 2(a) - 2(f), the input
16 layer 20 would have six or more neurons 26 depending on the
17 number of components required to represent each data set. The
18 hidden layer 22 also includes a plurality of neurons 28. The
19 number of neurons 28 in the hidden layer preferably equal the
20 number of neurons 26 in the input layer 20. In other words,
21 where the input layer 20 has six neurons 26, the hidden layer 22
22 will have six neurons 28. Each neuron 28 is connected to each of
23 the neurons 26. The output layer 24 is preferably formed by two
24 output neurons 30 with each output neuron 30 being connected to
25 each of the neurons 28. The information from the two output
26 neurons 30 represents a value of a predicted latitude and

1 longitude several hours in advance of the hurricane. The various
2 neurons in the layers 20, 22 and 24 are linked by weighted values
3 or links. The number of input, output, and hidden layer neurons
4 can be varied to improve the forecasting capability of the neural
5 network.

6 The neural network 14 may be implemented in any manner known
7 in the art. For example, the neural network 14 may be
8 implemented by a computer (not shown) which is preprogrammed with
9 software for creating the desired neural network, namely one
10 which can be trained using a well known back propagation
11 technique and which can also be used in a well known feed forward
12 manner. The software may process the input data to reach a
13 prediction as to the track of the hurricane in any desired
14 manner. The architecture of the software does not form part of
15 the present invention.

16 As previously discussed, the output layer 30 is used to
17 periodically generate an output signal 32 representative of a
18 predicted latitude and longitude several hours in advance of the
19 hurricane. The output signal 32 falls in a defined numerical
20 range which represents latitude and longitude values. For
21 example, neural network outputs between 0 and 1 may represent
22 latitude or longitude values between 0 and 180 degrees.

23 The system 10 preferably includes a device 16 for displaying
24 the predicted track of the hurricane generated by the output
25 layer 30 of the neural network 14. The display device 16 can be
26 any suitable display device known in the art such as a video

1 monitor and/or a printer. If desired, the display device 16 may
2 be omitted.

3 Finally, the system 10 includes database 18. The database
4 18 may be used for a variety of purposes. For example, it may be
5 used to store historical data which is used to train the neural
6 network 14. Additionally, it may be used to store the real-time
7 information being inputted into the neural network 14 as well as
8 the hurricane path predictions generated by the neural network
9 14. The stored hurricane track predictions may be used to later
10 train or retrain the neural network 14. The database 18 may be a
11 portion of the memory of the computer used to implement the
12 neural network 14. Alternatively, the data base 18 may comprise
13 a separate storage device such as a tape storage device.

14 Prior to use as a predictor of the track of a hurricane, the
15 neural network 14 must be trained to determine the neural network
16 parameters that provide the "best" tracks. Any back propagation
17 technique known in the art may be used to train the computer. A
18 back propagation technique is employed because the topology of
19 the neural network lends itself to supervised learning.

20 The data used to train the neural network comes from the
21 information about past hurricanes stored in the database 18. For
22 a first iteration, information from a previous hurricane is
23 inputted into the input layer 20 of the neural network 14. The
24 information which is inputted into the neural network 14
25 comprises historical information about the location of the center
26 of the hurricane, the velocity of the hurricane center, the

1 change in velocity in the hurricane center, the average wind
2 speed of the hurricane, the pressure in the center of the
3 hurricane, and the direction of the hurricane winds, all at a
4 point in time. Arbitrary weights are assigned to the links
5 between the various layers and a predicted track for the
6 hurricane is computed by the neural network. The error between
7 the predicted track for the hurricane and the actual, or known
8 historical track of the hurricane is then computed or calculated.

9 The internal weights in the neural network are then adjusted to
10 reduce the error. The process is repeated using input data
11 available for other times during the course of the hurricane
12 until the error reaches a predetermined acceptable level. Then,
13 information about a second hurricane track is inputted into the
14 neural network and the process is repeated. The training may be
15 repeated for as many iterations as desired. For example,
16 information from 25 to 100 different hurricanes may be inputted
17 into the neural network 14 to train it. Training continues until
18 the neural network is capable of producing a statistically
19 accurate output for previously unseen input data. At that point,
20 the neural network 14 is deemed to be trained and the knowledge
21 is stored in the internal weights or links. Typically, the
22 weight information is stored for future use.

23 In a preferred embodiment of the present invention, the
24 information inputted into the neural network 14 to train it is
25 about hurricanes in a specific geographic region with a history

1 of hurricane activity, thereby constraining the training data set
2 to that particular area.

3 After training is completed, the system 10 is used to
4 predict the track of a hurricane using the aforementioned input
5 data from the module 12 and the stored weight information. The
6 input data is preferably updated periodically, such as every two
7 hours. The neural network 14 is used to generate a predicted
8 track for the hurricane at specific intervals, such as every two
9 hours.

10 Statistical methods for estimation do not typically
11 incorporate historical data into the estimation process. One of
12 the advantages to the system of the present invention is that the
13 neural network 14 can be trained with a subset of historical
14 data. This subset can include as much data as necessary to
15 produce a statistically "good" track with a predefined degree of
16 accuracy. This approach captures the skill and experience
17 missing in statistical techniques used today.

18 While specific input parameters to the neural network 14
19 have been mentioned hereinbefore, it should be recognized that
20 other or additional input parameters may be used. For example,
21 other parameters such as amount of rainfall, storm surge
22 conditions, or wave height measurements may be used.

23 If desired, the output positional parameters produced by the
24 neural network 14 may be described in another coordinate system
25 like polar coordinates instead of longitude and latitude.

1 It is apparent that there has been provided in accordance
2 with the invention described herein a neural network hurricane
3 tracker which fully satisfies the means, objects and advantages
4 set forth hereinbefore. While the invention has been described
5 in connection with specific embodiments thereof, it should be
6 apparent that those skilled in the art may arrive at other
7 variations, alternatives, and modifications. It is intended to
8 embrace such variations, alternatives and modifications,

9

NEURAL NETWORK HURRICANE TRACKER

ABSTRACT OF THE DISCLOSURE

The present invention relates to a method and a system for predicting the path of a hurricane. The system includes sensors for gathering real-time data about the hurricane and supplying the data to a trained neural network for yielding a predicted path for the hurricane. The system further includes a device for displaying the predicted path of the hurricane. A method for using and training the neural network in the system is described.

In the method, the neural network is trained using information about hurricanes in a specific geographical area maintained in a database. The training involves inputting a plurality of parameters about at least one historical hurricane track and producing an output signal representative of a predicted hurricane path. An error is calculated between the output signal and the actual track and the internal weights of the neural network are adjusted to reduce the error.
