ON THE STABILITY OF A MACLAURIN SPHEROID OF SMALL VISCOSITY

P. H. Roberts and K. Stewartson

MRC Technical Summary Report #373
February 1963

Madison, Wisconsin
ABSTRACT

The stability of a viscous Maclaurin spheroid is solved asymptotically for small kinematic viscosity, \( \nu \). It is shown that, in this limit, the frequency of oscillation, \( n \), with respect to the mode which becomes neutrally stable in the absence of viscosity at the point of bifurcation (where the eccentricity, \( e \), of the meridional section is approximately 0.8127), is

\[
n = n_0 + \frac{5\nu n_0^2}{\varphi(e)} + 0(\nu)
\]

(1)

In the foregoing formula, \( n_0 \) denotes the frequency in the absence of viscosity, \( a \) the radius of the equational section and \( \varphi(e) \) a certain function of \( e \) which changes sign at \( e = 0.8127 \) and is positive for smaller values of \( e \). From equation (1) it follows that the Maclaurin spheroid is indeed unstable beyond the point of bifurcation when viscosity is present.
ON THE STABILITY OF A MACLAURIN SPHEROID
OF SMALL VISCOITY

P. H. Roberts*
and
K. Stewartson**

1. INTRODUCTION.

It is well known that, for an incompressible fluid mass in a state of
uniform rotation and in equilibrium under its own gravitation, a spheroid of
revolution is an exact figure of equilibrium. This is the spheroid of Maclaurin.
The stability of these spheroids with respect to infinitesimal perturbations has
been investigated in a number of classical papers by Riemann (1860), Bryan
(1888) and Cartan (1922) (see also Lebovitz, [1961]). From these investigations
it is known that, in the absence of viscosity, the Maclaurin spheroids are
stable provided that the eccentricity, \(e\), of the meridional section is less than
0.9529; and that, when the eccentricity exceeds this limit, the Maclaurin
spheroids are unstable by oscillations of increasing amplitude (the period of
oscillation being, in fact, equal to the angular velocity \(\Omega\)). However, it
was known, even before the upper limit \(e = 0.9529\) was established by Bryan,
that the Maclaurin spheroid allows a neutral mode of oscillation at \(e = 0.8127\),
where the ellipsoids of Jacobi branch off.

The occurrence of a neutral mode for the Maclaurin spheroids at the point of bifurcation is suggestive; indeed, it was categorically stated by Thomson and Tait (1883, p. 333) that "the equilibrium in the revolutional figure is stable or unstable according as \( e \) is less than or greater than 0.81266." In definitely associating the occurrence of the neutral mode (for infinitesimal oscillations) with the onset of instability, Thomson and Tait clearly had the role of viscosity in mind. They state, for example, "if there be any viscosity, however slight, in the liquid or if there be any imperfectly elastic solid, however small, floating on it or sunk within it, the equilibrium in any case of energy either minimax or a maximum cannot be secularly stable: the only secularly stable configurations are those in which the energy is the minimum with given momentum." All these considerations became, of course, clarified by the investigations of Poincare which showed that, at the point of bifurcation of the Maclaurin sequence, it is possible to deform the Maclaurin spheroid into a body of the same angular momentum but of lower total energy. From this last fact one generally concludes that, should any dissipative mechanism be operative, then it would indeed operate and induce the transition to the state of lower energy, i.e. instability will arise. In other words, the belief and the conjecture is that, were one to investigate the stability of a viscous Maclaurin spheroid (again for infinitesimal perturbations) then one would find that it becomes unstable (with an initial infinitesimal amplitude increasing exponentially with time) when one surpasses the point of bifurcation. This last argument is usually illustrated by simple mechanical examples (cf. Jeans, [1929], p. 201). While
the suggestion that the objects should be unstable under the circumstances envisaged is very reasonable, it is not a forgone conclusion that motions consistent with the equations of hydrodynamics do exist which will allow instability: examples are known when a normal mode analysis proves stability in circumstances when an energy argument would suggest instability (cf., Chandrasekhar, 1961, S103). And finally, the energy argument provides no basis for estimating the growth rates of the unstable mode when viscosity is operative. For these reasons, we shall consider in this paper the stability of the Maclaurin spheroid allowing for viscosity in the limit when it is small; the assumption of small viscosity is made, for the problem is then tractable by a boundary layer argument.
II. THE EQUILIBRIUM STATE

Let \((x, y, z)\) be cartesian co-ordinates in which the \(z\)-axis is parallel to \(\Omega\), the angular velocity of the spheroid, and in which the origin is at the center of that body. The equation of the surface, \(S_e\), of the spheroid is then of the form

\[
\frac{\tilde{\omega}^2}{a^2} + \frac{z^2}{c^2} = 1, \tag{2.1}
\]

where \(\tilde{\omega} = (x^2 + y^2)^{\frac{1}{2}}\). It is convenient, for the later discussion, to introduce oblate spheroidal co-ordinates here. For this purpose, define \(k\) and \(E\) by

\[
k = a^2 - c^2, \quad E = c/k. \tag{2.2}
\]

The following relations then exist between \(a, c, k, E\) and the eccentricity of the spheroid, \(e\):

\[
a = k(l + E^2)^{\frac{1}{2}}, \quad c = kE = a(l - e^2)^{\frac{1}{2}}, \quad k = ae, \quad \sin^{-1} e = \cot^{-1} E. \tag{2.3}
\]

Oblate spheroidal co-ordinates \((\zeta, \theta, \varphi)\) are defined by

\[
x = k(1 + \zeta^2)^{\frac{1}{2}} \sin \theta \cos \varphi,
\]

\[
y = k(1 + \zeta^2)^{\frac{1}{2}} \sin \theta \sin \varphi, \tag{2.4}
\]

\[
z = k \zeta \cos \theta,
\]
\(0 < \theta \leq \pi, 0 < \phi < 2 \pi\). They form an orthogonal curvilinear system, right-handed in the order \((\zeta, \theta, \phi)\), and having scale factors \(h_\zeta, h_\theta, h_\phi\), given by

\[
h_\zeta = k \left( \frac{\zeta^2 + \mu^2}{1 + \zeta^2} \right)^{\frac{1}{2}}, \quad h_\theta = k(\zeta^2 + \mu^2)^{\frac{1}{2}}, \quad h_\phi = k(1 + \zeta^2)^{\frac{1}{2}}(1 - \mu^2)^{\frac{1}{2}}, \quad (2.5)
\]

where \(\mu = \cos \theta\). The surfaces of equal \(\zeta\) are a confocal system of spheroids and, in virtue of the definitions \((2.2)\), \(S_\phi\) is the particular member

\[
\zeta = E \quad (2.6)
\]

of this system.

Since the material of which the spheroid is composed is supposed to be incompressible and of uniform density \(\rho\), the equation of hydrostatic equilibrium is simply

\[
\frac{p - V}{\rho} - \frac{1}{2} \Omega^2 \omega^2 = \text{constant}, \quad (2.7)
\]

where \(p\) is the pressure, and \(V\) is the gravitational potential. Now the potential within the oblate spheroid \((2.1)\) is given by (see, for example, Routh, 1922, Art. 211)

\[
\frac{V}{\pi G \rho a^2 c} = I - A_1 \omega^2 - A_3 z^2, \quad (2.8)
\]

where \(I, A_1\) and \(A_3\) are constants given by
Thus, equation (2.7) may be rewritten in the form

\[ \frac{p}{\rho} = \text{constant} - \pi G \rho a^2 c [(A_1 - \frac{\Omega^2}{2\pi G \rho a^2 c}) \tilde{w}^2 + A_3 z^2] . \] (2.10)

However, since \( p \) must vanish everywhere on the equilibrium surface (2.1), it must be possible to rewrite equation (2.10) in the form

\[ \frac{p}{\rho} = \pi G \rho a^2 c A_3 [1 - \frac{\tilde{w}^2}{a^2} - \frac{z^2}{c^2}] . \] (2.11)

Comparing the expressions (2.10) and (2.11), we conclude that

\[ a^2 (A_1 - \frac{\Omega^2}{2\pi G \rho a^2 c}) = c^2 A_3 , \] (2.12)

i.e., by equations (2.9),

\[ \Omega^2 = \frac{2\pi G \rho}{e^3} (1-e^2)^{\frac{1}{2}} [(3-2e^2) \sin^{-1} e - 3e(1-e^2)^{\frac{1}{2}}] . \] (2.12)
III. PERTURBATIONS ABOUT EQUILIBRIUM

Suppose that the equilibrium solution of Section II is infinitesimally perturbed. The fluid velocity $\mathbf{u}$ in the subsequent motion will satisfy the incompressibility requirement

$$\operatorname{div} \mathbf{u} = 0 ,$$

(3.1)

and also the linearized Navier-Stokes equation

$$\frac{\partial \mathbf{u}}{\partial t} + 2\Omega \times \mathbf{u} - \nabla \Pi = -\nabla \cdot \mathbf{u} + \nu \nabla^2 \mathbf{u} ,$$

(3.2)

where $\nu$ denotes the kinematic viscosity, and

$$\Pi = \frac{\rho - \nu}{\rho} - \frac{1}{2} \Omega^2 \omega^2 .$$

(3.3)

Thus $\mathbf{u}$ must satisfy boundary conditions on the perturbed surface $S$ of the fluid. These require that the normal velocity of the fluid on $S$ should equal the normal velocity of the boundary $S$ itself. They also require that the normal components of the mechanical stress tensor should vanish on $S$. Introducing the rate of strain tensor $R_{ij}$, defined by

$$R_{ij} = \frac{1}{2} \left( \frac{\partial u_i}{\partial x_j} + \frac{\partial u_j}{\partial x_i} \right) ,$$

(3.4)

the viscous stress tensor is $\nu \rho R_{ij}$. Since $\mathbf{u}$ is a quantity of the first order of smallness, the differences in the values of $R_{ij}$ and $R_{ij}$ on $S$ from their value on $S_e$ are of second order of smallness, and can therefore be neglected.
It follows that the demands that \( \nu p R_{\xi \theta} \) and \( \nu p R_{\xi \phi} \) should vanish on \( S \) require

\[
\text{either } \nu = 0, \text{ or } [R_{\xi \theta}]_{S_e} = [R_{\xi \phi}]_{S_e} = 0 ,
\]

(3.5)

where we have used \([U]_V\) to denote the value of a quantity \( U \) on a surface \( V \).

The remaining stress condition is

\[
[p - 2 \nu p R_{\xi \zeta}]_{S} = 0
\]

(3.6)

and it is again convenient to extrapolate this condition back to the reference surface \( S_e \). For this purpose we write \( p \) and \( V \) in the forms

\[
p = p_e + \delta p, \quad V = V_e + \delta V ,
\]

(3.7)

where \( p_e \) and \( V_e \) are the values of \( p \) and \( V \) in the equilibrium solution (cf. eqs. [2.8] and [2.11]). We also introduce \( \xi(t, \xi) \) the displacement of a particle of fluid at time \( t \) from its equilibrium position \( \xi \). Clearly we have

\[
\dot{\xi} = \frac{\partial \xi}{\partial t} ,
\]

(3.8)

to first order. Moreover, it is evident that

\[
[p]_S \equiv [p_e]_S + [\delta p]_{S_e}
\]

\[
\equiv [p_e + \xi \cdot \text{grad } p_e]_{S_e} + [\delta p]_{S_e}
\]

(3.9)
Thus condition (3.6) is equivalent to

$$ [p_e + \xi \cdot \text{grad } p_e + \delta p - 2\nu \rho R \xi]_S = 0 , \quad (3.10) $$

or, since equations (2.7) and (3.3) imply that

$$ \Pi = \left( \frac{p_e}{\rho} - V_e - \frac{1}{2} \Omega^2 \omega^2 \right) + \left( \frac{\delta p}{\rho} - \delta V \right) = \frac{\delta p}{\rho} - \delta V + \text{Const}, \quad (3.11) $$

we have (absorbing the constant on the right-hand side of eq. [3.11])

$$ [\phi + \rho \Pi - 2\nu \rho R \xi]_S = 0 , \quad (3.12) $$

where

$$ \phi = \rho \delta V + \xi \cdot \text{grad } p_e \quad (3.13) $$

The significance of $\phi$ may be seen by considering the changes $\delta W$ in the gravitational energy $W$ of the configuration

$$ W = -\frac{1}{2} G_p^2 \int_V \int_V \frac{dx dx'}{|x-x'|} , \quad (3.14) $$

consequent upon the deformation $\xi$. It is evident from equation (3.14) that

$$ \delta V = -G_p^2 \int_{V_e} \int_{V-e} \frac{dx dx'}{|x-x'|} $$

$$ = -p \int_{V_e} \delta V(x) dx . \quad (3.15) $$
On the other hand, the work done against the pressure forces in the deformation $\xi$ is, to first order,

$$-\int_V \xi \cdot \text{grad} p_e \, dx.$$  

(3.16)

Thus the sum of (3.15) and (3.16), namely $\int_V \Phi \, dx$, is the work required in order to subject the equilibrium configuration quasi-statically to the $\xi$ deformation. In the dynamical problem studied herein, it will equal the sum of two parts, namely, the decrease in kinetic energy and the energy degraded to heat by the action of viscosity.

IV. GRAVITATIONAL EFFECTS

In calculating $\delta V$, the surface deformation may be divided into its harmonic components $P_n^m(\mu) \, e^{i m \phi}$, and each may be considered separately. We will write, therefore,

$$\left[\xi_{S_e}\right] = \frac{1}{h_\xi} K_{n,m}^p \, P_n^m(\mu) \, e^{i m \phi},$$  

(4.1)

where

$$K_{n,m} = \frac{(2n+1)(n-m)!}{4\pi(n+m)!} \int_{-1}^{1} \int_{0}^{2\pi} d\mu \, d\varphi \, \left[\xi_{S_e}\right] \, P_n^m(\mu) \, e^{-i m \phi}.$$  

(4.2)

The gravitational effect of this displacement may be likened to the addition of a surface mass distribution to $S_e$ of density $\rho[\xi_{S_e}]$. The gravitational
potential to which this gives rise must be a continuous solution of Laplace's equation, and must therefore be of the form

\[ \delta V = \begin{cases} 
C_{n,m} \frac{Q_n^m(i\xi)}{Q_n^m(iE)} P_n^m(\mu) e^{im\varphi}, & \xi \geq E, \\
C_{n,m} \frac{P_n^m(i\xi)}{P_n^m(iE)} P_n^m(\mu) e^{im\varphi}, & \xi \leq E, 
\end{cases} \] (4.3)

where \( Q_n^m(i\xi) \) denotes the associated Legendre function of the second kind of the orders \( n \) and \( m \) indicated, and of imaginary argument. For complex arguments, we adopt Hobson's definitions of \( P_n^m(z) \) (see, for example, Hobson, 1931, § 54):

\[ P_n^m(z) = (z^2 - 1)^{\frac{1}{2}m} \frac{d^n}{dz^n} \frac{P_n(z)}{z^m}, \quad Q_n^m(z) = (z^2 - 1)^{\frac{1}{2}m} \frac{d^n}{dz^n} \frac{Q_n(z)}{z^m}. \]

The Wronskian relationship between these functions takes the form

\[ P_n^m(z) \frac{d}{dz} Q_n^m(z) - Q_n^m(z) \frac{d}{dz} P_n^m(z) = \frac{(-)^m(n+m)!}{(n-m)!} \frac{1}{1 - z^2} \] (4.4)

In order to determine the constant \( C_{n,m} \) appearing in the solution (4.3), we apply Gauss' theorem to an elementary volume containing the surface mass distribution:
which, using equation (4.3), reduces to

\[ C_{n,m} \left[ \frac{1}{Q_n} \frac{d}{d\zeta} Q_n^{m(i\zeta)} - \frac{1}{P_n} \frac{d}{d\zeta} P_n^{m(i\zeta)} \right]_{\zeta=\text{E}} = -4\pi G \rho \left[ \xi_{\text{E}} \right]_{\zeta=\text{E}}. \]  

By using relation (4.4), we finally obtain

\[ C_{n,m} = \frac{4\pi G \rho (-1)^m (n-m) \frac{d}{d\zeta}}{e^2 (n+m)!} K_{n,m} P_n^{m(i\zeta)} Q_n^{m(i\zeta)} \]  

It follows that

\[ [\delta V]_{\xi} = \frac{4\pi G \rho 2}{e^2} \frac{(-1)^m (n-m)!}{(n+m)!} K_{n,m} P_n^{m(i\zeta)} Q_n^{m(i\zeta)} P_n^{m(\mu)} e^{im\varphi}. \]  

In order to calculate \([\Phi]_{\xi}\), we note that, according to equation (2.11),

\[ \text{grad } p_e = -\frac{2}{e} G \rho 2 a^3 (1-e^2) A_3 h \xi, \]  

where \(h \xi\) is a unit vector in the direction of increasing \(\zeta\).

Thus, by equation (4.1),

\[ [\xi; \text{grad } p_e]_{\xi} = -\frac{2\pi}{e} G \rho 2 a^3 (1-e^2) A_3 K_{n,m} P_n^{m(\mu)} e^{im\varphi}. \]  

Hence

\[ [\Phi]_{\xi} = \frac{4\pi G \rho 2}{e^2} \left[ \frac{(-1)^m (n-m)!}{(n+m)!} P_n^{m(i\zeta)} Q_n^{m(i\zeta)} \frac{1}{2} a^3 (1-e^2)^2 A_3 \right] K_{n,m} P_n^{m(\mu)} e^{im\varphi}. \]  

(4.14)
In the studies which follow, we will be particularly concerned with the case \( n = m = 2 \). For this harmonic, we have

\[
P_2^2(iE) = -3(1+E^2) , \quad Q_2^2(iE) = i[3(1+E^2)\cot^{-1}E - (5E+3E^3)] / (1+E^2)
\]

and \( \phi \) takes the form

\[
[\Phi]_e = -\frac{\pi G \rho^2}{2e^3} [e(1-e^{-2})^\frac{1}{2}(3+10e^2)-(3+8e^2-8e^4)\sin^{-1}e] K_2 e^{2i\varphi} .
\]

(4.13)

V. THE INVISCID SOLUTIONS

Cartan (1922) and others (see, for example, Bryan, 1888) have examined the case \( \nu = 0 \) in great detail, and have shown that all the normal modes of oscillation can be generated from polynomial solutions of Poincare's differential equation:

\[
\begin{align*}
\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + (1 + \frac{4\Omega^2}{s^2}) \frac{\partial^2}{\partial z^2} = 0 ,
\end{align*}
\]

(5.1)

where \( s = \partial / \partial t \). Since boundary conditions (3.5) are automatically satisfied when \( \nu = 0 \), there is only one condition (viz. eq. [3.12]) to be applied on \( S_e \), and this determines \( s^2 \) for the normal mode considered. Although

* That Poincare's equation arises may be seen simply by solving eq. [3.2] for \( u \) in terms of grad \( \Pi \) and substituting the result into eq. [3.1].
equation (5.1) is hyperbolic when \(-4 \Omega^2 < s^2 < 0\) and the boundary condition (3.12) is the Dirichlet type, Cartan was able to establish that, even in this case, the polynomial solutions are unique.

We can illustrate the solution simply for the important case

\[ \Pi = h(x+iy)^2, \quad (h = \text{constant}), \quad (5.2) \]

which evidently satisfies equation (5.1). From equation (3.2) we find

\[ u_x = \frac{-2h(x+iy)}{(s-2i\Omega)}, \quad u_y = \frac{-2h(x+iy)}{(s-2i\Omega)}, \quad u_z = 0. \quad (5.3) \]

It should be noticed in passing that this solution satisfies

\[ \nabla^2 u = 0. \quad (5.4) \]

According to equation (5.3), \(u_\xi\) is given by

\[ h_\xi u_\xi = a^2 e(1-e^2)^{\frac{1}{2}} \left( \frac{x}{a^2} u_x + \frac{y}{a^2} u_y + \frac{z}{c^2} u_z \right) \]

\[ = -\frac{2e^{3(1-e^2)^{\frac{1}{2}}}}{(s-2i\Omega)} h(x+iy)^2. \quad (5.5) \]

Thus, on \(S_e\) we have

\[ [\Pi]_{S_e} = \frac{1}{3} a^2 h_{P_2}^2(\mu) e^{2i\varphi} \quad (5.6) \]

\[ [h_\xi u_\xi]_{S_e} = -\frac{2a^2 h_{(1-e^2)^{\frac{1}{2}}} p_{P_2}^2(\mu) e^{2i\varphi}}{3(s-2i\Omega)}. \quad (5.7) \]
From equation (5.7), in the notation of equation (4.1), we find

\[ K_{2,2} = -\frac{2a^2h\epsilon(1-\epsilon^2)^{\frac{1}{2}}}{3s(s-2i\Omega)}. \]  \hspace{1cm} (5.8)

Thus drawing together equations (5.6), (5.8), (4.13) and (3.12), we find

\[ \frac{1}{3} \rho s^2 h + \frac{2a^2 e(1-e^2)^{\frac{1}{2}}}{3s(s-2i\Omega)} \frac{h\pi G\rho^2}{2e} \left[ e(1-e^2)^{\frac{1}{2}}(3+10e^2)-(3+8e^2-8e^4)\sin^{-1}e \right] = 0, \]

i.e.

\[ s(s-2i\Omega) = -\frac{\pi G\rho}{e^5} (1-e^2)^{\frac{1}{2}} \left[ e(1-e^2)^{\frac{1}{2}}(3+10e^2)-(3+8e^2-8e^4)\sin^{-1}e \right]. \]  \hspace{1cm} (5.9)

This is Cartan's result (loc. cit. p. 338). Writing it in the form

\[ s(s-2i\Omega) + Q = 0 \]  \hspace{1cm} (5.10)

we find that either \( s = s_a \) or \( s = s_b \) where

\[ s_a = i[\Omega-(Q+\Omega^2)^{\frac{1}{2}}] = \text{in}_a \text{(say)}, \]  \hspace{1cm} (5.11a)

\[ s_b = i[\Omega+(Q+\Omega^2)^{\frac{1}{2}}] = \text{in}_b \text{(say)}. \]  \hspace{1cm} (5.11b)

At the point of bifurcation of the Maclaurin sequence, \( Q \) is zero, the root (5.11a) is therefore zero, and the spheroid is neutrally stable. Beyond bifurcation, \( s_a \) is again non-zero, and the spheroid is again stable. However, if the argument of Thomson and Tait is correct (see Section I), viscosity should introduce into root (5.11a) a real part which changes sign from negative to positive on passing through the point of bifurcation. This possibility is studied in the next section.
Before leaving this solution it is useful to compute the rate of strain tensor. According to equations (3.4) and (5.3) we find that, in the cartesian coordinate system (x, y, z)

\[
R_{ij} = -\frac{2h}{(s-2i\eta)} \begin{pmatrix}
1 & 1 & 0 \\
1 & -1 & 0 \\
0 & 0 & 0
\end{pmatrix}
\]  

(5.12)

The rate of strain is thus constant throughout the spheroid. It may be written simply in dyadic form

\[
R_{ij} = -\frac{2h}{(s-2i)} \mathcal{Q}_i \mathcal{Q}_j
\]

(5.13)

where \( \mathcal{Q} \) is a vector whose (x, y, z) components are

\[
\mathcal{Q} = (1, 1, 0)
\]

(5.14)

and whose (\( \xi, \theta, \varphi \)) components are therefore

\[
\mathcal{Q} = (\sin \psi, \cos \psi, 1) e^{i\varphi}
\]

(5.15)

where

\[
\cos \psi = \frac{\Omega_\xi}{\Omega} = \mu \left( \frac{1+\xi^2}{\xi^2+\mu^2} \right)^{\frac{1}{2}}, \quad \sin \psi = \frac{\Omega_\omega}{\Omega} = \left( \frac{1-\mu^2}{\xi^2+\mu^2} \right)^{\frac{1}{2}}
\]

(5.16)

By equations (5.13) and (5.15), we find immediately that
VI. THE EFFECT OF A SMALL VISCOSITY

The solution obtained in Section V for an inviscid fluid can, in principle, be modified in two ways when the fluid has a small kinematic viscosity $\nu$. First, the equations of motion with $\nu = 0$ may not be satisfied by the inviscid solution so that correction terms of order $\nu$ are required. In the present problem, however, in which we are concerned with the solution (5.3), the viscous terms of equation (3.2) vanish identically in virtue of equation (5.4), and no such modifications of the inviscid solution are required. Second, the boundary conditions which must be satisfied by the solution for a viscous fluid include the requirements (cf. eq. [3.5]) that the tangential components of $R_{ij}$ must vanish at the free surface $S$. If, as in the present problem, these conditions are not satisfied by the inviscid solution, then a boundary layer in which viscous effects are significant must be introduced in order to make the necessary adjustments to the tangential stresses. We suppose that the leading terms in the boundary layer vanish at its inner edge so that the inviscid solution is not modified to the order of these terms. However, in satisfying the conditions on the tangential stress components, the condition on the normal component is
invalidated, albeit to a higher order in $\nu$. In order to correct this, all the solutions of the inviscid problem involving the surface harmonics for which $m = 2$ must be excited, including the one with $n = 2$. Equation (5.9) is consequently modified.

For small values of the viscosity ($\nu << \frac{a^2 \Omega}{2}$) it is accordingly convenient to proceed as follows. Write

$$u = u_0 + u_1, \quad \Pi = \Pi_0 + \Pi_1, \quad \phi = \phi_0 + \phi_1, \quad (6.1)$$

where $u_0$ and $\Pi_0$ are solutions of the inviscid equations with $m = n = 2$ but which do not obey equation (5.9), and $u_1$ and $\Pi_1$, are the leading terms of the modification due to viscosity which vanish in the interior of the fluid. In addition $\phi_0$ is the value of $\phi$ arising from the perturbation of the free surface due to $u_0$, with a corresponding definition for $\phi_1$. Then, from equation (3.12), we have

$$[\phi + \rho \Pi - 2\nu \rho R_0 \xi \xi]_e = 0, \quad (6.2)$$

i.e.

$$[\phi_0 + \rho \Pi_0]_e + [\phi_1 + \rho \Pi_1 - 2\nu \rho R_0 \xi \xi]_e = 0, \quad (6.3)$$

as the condition on the normal stress to be satisfied by the solution. We are particularly interested in the harmonic $n = m = 2$, and so we multiply equation (6.3) by $P_2(\mu)e^{-2i\phi}$ and integrate over the surface of the spheroid, obtaining
\[ \frac{1}{3} \rho s^2 h[1 + \frac{Q}{s(s-2\Omega)}] + \gamma = 0 \]  

(6.4)

where we have used the theory of Section V. Here \( \gamma \) is the contribution from the second term of equation (6.3):

\[ \gamma = \frac{5}{32\pi} \int_{-\infty}^{\infty} du \int_{0}^{2\pi} d\varphi [\Phi - 2\nu \rho R_0 \xi \zeta]_e (1-\mu^2) e^{-2i\varphi}. \]  

(6.5)

In the normal mode theory, it is assumed that time enters the dependent variables through the factor \( e^{st} \), so that

\[ [h_\xi \xi]_e = \frac{1}{s} [h_\xi \xi]_e. \]  

(6.6)

Using equations (4.1) and (4.13) and the definition of \( Q \) (cf. eqs. [5.9] and [5.10]), it follows that

\[ \gamma = \frac{5\rho}{32\pi} \int_{-\infty}^{\infty} du \int_{0}^{2\pi} d\varphi [\Pi_1 - \frac{(1+E^2)Q}{2sE} (h_\xi u_1 \xi)]_e - 2\nu R_0 \xi \zeta]_e (1-\mu^2) e^{-2i\varphi}. \]  

(6.7)

Our main purpose here is to evaluate \( \gamma \).

An examination of equations (3.1), (3.2) and (3.5) suggests that we assume that the boundary layer is of the conventional type in which

\[ u_{1\theta} = O(v^{3/2}), \quad u_{1\varphi} = O(v^{3/2}), \quad \theta/\theta = O(v^{-3/2}), \]  

\[ \theta/\theta = O(1), \quad \theta/\varphi = O(1), \]  

(6.8)

so that

\[ u_{1\xi} = O(v), \quad \Pi_1 = O(v) \]  

(6.9)

all orders of magnitude referring to the dependence upon \( v \).
The leading terms of the $\theta$, $\phi$ and $\zeta$ components of the equations of momentum (3.2) and the complete equation of continuity (3.1) may then be written

\[
\left(\frac{v}{h_\zeta}\frac{\partial^2}{\partial t^2} - s\right) u_{1\theta} + 2\Omega \cos \psi u_{1\phi} = 0 ,
\]

(6.10)

\[
\left(\frac{v}{h_\zeta}\frac{\partial^2}{\partial t^2} - s\right) u_{1\phi} - 2\Omega \cos \psi u_{1\theta} = 0 ,
\]

(6.11)

\[
\frac{1}{h_\zeta} \frac{\partial \Pi_1}{\partial t} = 2\Omega \sin \psi u_{1\phi} ,
\]

(6.12)

\[
(1+E^2)h_\zeta \frac{\partial u_{1\zeta}}{\partial t} - \frac{\partial}{\partial \mu} [(1-\mu^2)^{\frac{1}{2}} h_\theta u_{1\theta} + \frac{2k(E^2 + \mu^2)u_{1\phi}}{(1+E^2)^{\frac{1}{2}}(1-\mu^2)^{\frac{1}{2}}} = 0 .
\]

(6.13)

In all of these equations $h_\zeta$ and $h_\theta$ are to be evaluated at $\zeta = E$, and are therefore functions of $\mu$ alone. Further, in equation (6.13), we have made use of the property that all dependent variables depend on $\varphi$, only though the factor $e^{2i\varphi}$. Combining equations (6.12) and (6.13) we obtain

\[
\frac{\partial}{\partial t} \left\{(1-\mu^2) \left[ \Pi_1 - \frac{(1+E^2)Q}{2sE} h_\zeta u_{1\zeta} \right] \right\}
\]

\[
= 2h_\zeta \sin \psi (1-\mu^2) u_{1\phi} + \frac{Qh_\zeta}{sE^2} (E^2 + \mu^2) \sin \psi (iu_{1\phi} - \cos \psi u_{1\theta})
\]

\[
- \frac{kQ}{2sE} \frac{\partial}{\partial \mu} \left[ (1-\mu^2)^{\frac{1}{2}} (E^2 + \mu^2)^{\frac{1}{2}} u_{1\theta} \right] .
\]

(6.14)
Anticipating that \( \gamma \) is of order \( \nu \), we may assume for the purposes of simplifying equation (6.14) that \( Q = -s(s-2i\Omega) \) (cf. eq. 5.10), whence

\[
\frac{\partial}{\partial \zeta} \left\{ (1-\mu^2) \left[ \Pi_0 - \frac{(1+E^2)Q}{2sE} h_\zeta u_{17} \right] \right\} = \frac{(E^2+\mu^2)h_\zeta \sin \psi}{2E^2} \left[ (u_{10}-iu_{17})(1+\cos \psi)(s-2i\Omega) \right.
\]

\[
\left. - (u_{10}+iu_{17})(1-\cos \psi)(s+2i\Omega \cos \psi) \right]
\]

\[
+ \frac{k(s-2i\Omega)}{2E} \left[ (1-\mu^2)^3/2(E^2+\mu^2)^{1/2} u_{10} \right]. \tag{6.15}
\]

The values of \( u_{10} \) and \( u_{17} \) required for the evaluation of the right-hand side of equation (6.15) follow from equations (6.10) and (6.11). Write

\[
\frac{\nu^2}{h_\zeta^2} = s+2i\Omega \cos \psi, \quad \frac{\nu^2}{h_\zeta^2} = s-2i\Omega \cos \psi, \tag{6.16}
\]

where the real parts of \( \alpha \) and \( \beta \) are both positive. The general solution of equations (6.10) and (6.11) which vanishes when \( \nu^{-\frac{1}{2}}(\zeta-E) \) is large and positive is then

\[
u_{10} = \frac{1}{2} \mathcal{A} e^{\alpha(\zeta-E)} + \frac{1}{2} \mathcal{B} e^{\beta(\zeta-E)} ,
\]

\[
u_{17} = \frac{1}{2} i\mathcal{A} e^{\alpha(\zeta-E)} + \frac{1}{2} i\mathcal{B} e^{\beta(\zeta-E)} . \tag{6.17}
\]
The values of the coefficient $A(\mu, \varphi)$ and $B(\mu, \varphi)$ are found from the condition that the tangential components of stress vanish at $\zeta = E$. Using equations (5.17), we have

\[
\frac{1}{4k_\zeta}(aA + \beta B) = \frac{2h \sin \psi \cos \psi}{s-2i\Omega} e^{21\varphi},
\]

\[
\frac{1}{4k_\zeta}(aA - \beta B) = -\frac{2ih \sin \psi}{s-2i\Omega} e^{21\varphi},
\]

and consequently

\[
A = \frac{4khE}{\alpha(1+E^2)^{\frac{1}{2}}(s-2i\Omega)} (\cos \psi - i)(1-\mu)^{\frac{1}{2}} e^{21\varphi}
\]

\[
B = \frac{4khE}{\beta(1+E^2)^{\frac{1}{2}}(s-2i\Omega)} (\cos \psi + 1)(1-\mu)^{\frac{1}{2}} e^{21\varphi}
\]

It is noted that the a priori assumptions (6.8) about the boundary layer have led to a reasonable solution which may easily be shown to be consistent provided neither $\alpha$ nor $\beta$ vanishes, i.e. if we write

\[
s = 2i\Omega \cos \psi_0, \quad (0 < \psi_0 < \Pi)^* \]

provided we exclude the neighborhood of the singularities $\psi = \psi_0$ and $\psi = \Pi - \psi_0$

* $\psi_0$ is real for the range $0.4285 < e < 0.9529$ ... of eccentricity. Since this range contains the point of bifurcation, the singularities defined by equations (6.20) are germane to our discussion.
These zones require special treatment which we shall postpone until the next section. We merely observe here that their contribution to \( \gamma \) is of order \( \nu^\frac{1}{2} \).

Substituting the results (6.17) and (6.19) into the first term appearing on the right-hand side of equation (6.15), integrating with respect to \( \zeta \) from \(-\infty \) to 0, and noting that \( \Pi, \) and \( u_{1\zeta} \) vanish in the interior of the fluid, we find that

\[
(1-\mu^2) \left[ \Pi_1 - \frac{(1+E^2)Q}{2sE} h_{\zeta} u_{1\zeta} \right]_{S_e}
\]

\[
= \frac{2h_{\zeta} h_{\nu} (1+E^2)^{\frac{1}{2}} (1-\mu)^{\frac{1}{2}} \sin \psi e^{2i\varphi}}{kE(s-2i\Omega)} \left[ (1+\cos \psi)^2 + (1-\cos \psi)^2 \right] + \int_{-\infty}^{0} \frac{h(s-2i\Omega) \partial}{2E} \left[ (1-\mu) \left( (E^2 + \mu)^{\frac{1}{2}} u_{1\Theta} \right) \right] d\zeta .
\]  

(6.21)

The determination of \( \gamma \) is completed by using the form of \( R_{o\zeta \zeta} \) given by equation (5.17)

\[
[2 R_{o\zeta \zeta}]_{S_e} = -\frac{4h_{\nu} E^2 (1-\mu)}{(E^2 + \mu^2)(s-2i\Omega)} e^{2i\varphi} ,
\]  

(6.22)

and adding it to equation (6.21) giving

\[
\rho(1-\mu^2) \left[ \Pi_1 - \frac{(1+E^2)Q}{2sE} h_{\zeta} u_{1\zeta} - 2\nu R_{o\zeta \zeta} \right]_{S_e}
\]

\[
= \frac{8h_{\nu} \rho}{(s-2i\Omega)} (1-\mu)^{\frac{1}{2}} e^{2i\varphi} + \int_{-\infty}^{0} \frac{h_{\nu} (s-2i\Omega) \partial}{2E} \left[ (1-\mu) \left( (E^2 + \mu)^{\frac{1}{2}} u_{1\Theta} \right) \right] d\zeta .
\]  

(6.23)
Carrying out the integration (6.5), assuming that the orders of integration with respect to \( \zeta \) and \( \mu \) can be inverted, we obtain

\[
\gamma = \frac{10h\nu \rho}{3(s-2\Omega)} ,
\]  

(6.24)

and hence, from equation (6.4),

\[
1 + \frac{Q}{s(s-2\Omega)} + \frac{10}{a^2(s-2\Omega)} = 0
\]  

(6.25)

is the modified dispersion relationship for the harmonic \( n = m = 2 \), neglecting powers of \( \nu \) above the first. Let one of its roots be

\[
s = s_0 + s_1
\]  

(6.26)

where \( s_0 \) is one of the roots (5.11) and \( s_1 \) is of order \( \nu \). On substituting into equation (6.25) and neglecting all powers of \( s_1 \) above the first, we find that

\[
s_1 = -\frac{5\nu s_0}{a^2(s_0-2\Omega)} = \frac{5\nu s_0^2}{a^2Q}
\]  

(6.27)

For small values of \( \Omega \), equation (5.11) implies that \( Q \approx -s_0^2 \). Thus, according to equation (6.27) \( s_1 \approx -5\nu/a^2 \), in agreement with the result of Lamb (1881) for the oscillations of a slightly viscous sphere (see also Chandrasekhar, 1959). Since \( s_0^2 \) is always negative up to the point of ordinary instability \( (e \approx 0.9529) \), the stability of the slightly viscous spheroid depends on the sign of \( Q \). Now \( Q \) is positive between \( e = 0 \) (the
sphere) and $e = 0.8127$ (where the Maclaurin sequence bifurcates) and is negative between this value of $e$ and $e = 0.9529$. It follows that, beyond bifurcation, the value of $s_1$ is real and positive so that oscillations of the Maclaurin spheroid in which the harmonic $n = m = 2$ are excited increase exponentially in amplitude with time in agreement with the conclusion based on the energy argument of Section I. Presumably once this instability sets in, the configuration moves towards the lower energy Jacobi state with the same angular momentum.

VII. THE SINGULAR CIRCLES

The theory of the boundary layer discussed in the previous section failed in the neighborhood of the circles of latitude $\psi = \psi_0$, and $\psi = \Pi - \psi_0$, where $\psi_0$ is defined by equation (6.20). One still expects the boundary layer to be vanishingly thin and the velocities in it to be vanishingly small as $v \to 0$, but the hypothesis (6.8) on which the theory is based needs modification. Let us concentrate attention on the zone $R_+$ in the neighborhood of $\psi = \psi_0$ and suppose that, instead of assumption (6.8),

$$\frac{\partial}{\partial \zeta} = o(v^{-p}), \quad \frac{\partial}{\partial \mu} = o(v^{-q}),$$

(7.1)

where $1/2 > p > q > 0$; thus we expect the boundary layer to be thicker in $R_+$ and rapid changes to occur in the $\mu$-direction but that the most rapid changes still occur in the $\zeta$-direction. It will be shown that $p = 2/5$, $q = 1/5$ leads to a consistent picture.
Further we shall assume that

\[ u_{1\theta} = o(\nu^r), \quad u_{1\phi} = o(\nu^r), \]  

\[ (7.2) \]

where \( r > 0 \). The equation of continuity (6.13) may now be written as

\[ \frac{1}{h} \frac{\partial u_{1\zeta}}{\partial \zeta} - \frac{(1-\mu) \frac{1}{2}}{h} \frac{\partial u_{1\theta}}{\partial \mu} = 0 \]

\[ (7.3) \]

where \( h \) and \( h_\theta \) are now constants, so that \( u_{1\zeta} = o(\nu^{p+q}) \). The equation of momentum in the \( \theta \)-direction reduces to

\[ \frac{\nu}{h} \frac{\partial^2 u_{1\theta}}{\partial \zeta^2} = su_{1\theta} - 2\Omega \cos \psi u_{1\phi} - \frac{(1-\mu) \frac{1}{2}}{h} \frac{\partial \Pi}{\partial \mu}; \]

\[ (7.4) \]

notice that in \( R^+ \), \( su_{1\theta} \leq 2\Omega \cos \psi u_{1\phi} \) by equations (6.16) and (6.17). It follows from equation (7.4) that \( \Pi_1 = o(\nu^{1+r-2p+q}) \). The equation of momentum in the \( \phi \)-direction reduces to

\[ \frac{\nu}{h} \frac{\partial^2 u_{1\phi}}{\partial \zeta^2} = su_{1\phi} + 2\Omega (\cos \psi u_{1\theta} + \sin \psi u_{1\zeta}); \]

\[ (7.5) \]

the pressure terms being of smaller order than the other terms of equation (7.5) since \( \partial \Pi_1 / \partial \phi = 2\Pi_1 \). The equation of momentum in the \( \zeta \)-direction is

\[ \frac{1}{h} \frac{\partial \Pi}{\partial \zeta} = 2\Omega u_{1\phi} \sin \psi, \]

\[ (7.6) \]
the viscous terms being negligible because $\frac{\partial \Pi_1}{\partial \zeta} \gg \frac{\partial \Pi_1}{\partial \mu}$ in virtue of assumption (7.1), and $u_{1\zeta} << u_{1\phi}$ in virtue of assumption (7.2) and equation (7.3). It is to be particularly noted that this equation is identical with equation (6.12), and that both the equations used to derive the basic result (6.14) hold also in $R_+$. Consequently, our aim here is to find the contribution of $R_+$ to equation (6.14). If we now eliminate $\Pi_1$ and $u_{1\zeta}$ from equations (7.3) to (7.6), and write

$$Z_+ = u_{1\theta} - iu_{1\phi}$$  \hspace{1cm} (7.7)

we find that

$$\frac{\nu}{h_2} \frac{\partial^3 Z_+}{\partial \zeta^3} = (s-2i\Omega \cos \psi) \frac{\partial Z_+}{\partial \zeta} - 2i\Omega \sin \psi \frac{h_2}{h_\theta} (1-\mu^2)^{\frac{1}{2}} \frac{\partial Z_+}{\partial \mu}. \hspace{1cm} (7.8)$$

Similarly, if

$$Z_- = u_{1\theta} + iu_{1\phi}$$  \hspace{1cm} (7.9)

$$\frac{\nu}{h_2} \frac{\partial^3 Z_-}{\partial \zeta^3} = (s+2i\Omega \cos \psi) \frac{\partial Z_-}{\partial \zeta} + 2i\Omega \sin \psi \frac{h_2}{h_\theta} (1-\mu^2)^{\frac{1}{2}} \frac{\partial Z_-}{\partial \mu}. \hspace{1cm} (7.10)$$

Thus, in equation (7.8), the last term on the right-hand side may be neglected except in $R_+$, and, in equation (7.9), the last term may be neglected except in $R_-$, the neighborhood of $\psi = \pi - \psi_0$. Concentrating attention on $R_+$, let us write $\psi = \psi_0 + \bar{\psi}$ where $\bar{\psi}$ is small. Then equation (7.8) simplifies to
\[
\frac{\nu}{h} \frac{\partial^3 Z_+}{\partial \zeta^3} = 2i \Omega \sin \psi_0 \frac{\partial Z_+}{\partial \zeta} - \frac{2i \Omega}{kE} h \sin \psi_0 \frac{\partial Z_+}{\partial \psi}.
\] (7.10)

From a comparison of the orders of magnitude of the three terms composing equation (7.10), and by using the assumed properties (7.1), we have

\[a = \frac{2}{5}, \quad b = \frac{1}{5}.\] (7.11)

Outside \(R_+\)

\[Z_+ = B e^{\theta(\zeta - E)},\] (7.12)

by equations (6.17). Consequently on the edge of \(R_+\) where \(|\psi - \psi_0|\) is small but \(v^{-1/5} \psi\) is large,

\[Z_+ \approx B_1 v^{1/2} \exp[\{2i \Omega h^2 \sin \psi_0 \frac{\psi}{v} \}^{1/2} (\zeta - E)\] (7.13)

where \(B_1\) is a factor of order unity. Comparing the orders of magnitude, it follows that

\[Z_+ = o(v^{2/5}).\] (7.14)

in \(R_+\). Moreover \(\partial Z_+ / \partial \zeta = o(1)\) in \(R_+\), as it must be since it is required to play a part in the cancellation of the tangential stresses. Although it has not been explicitly evaluated, the determination of \(Z_+\) in \(R_+\) seems to be a properly posed problem since, for not only do we have the behaviors (7.13) to determine the relevant solution of equation (7.10) at the edges of \(R_+\), but we
also have $Z_+ \to 0$ as $\zeta \to -\infty$ and, finally, $\partial Z_+ / \partial \zeta$ is known stress on $\zeta = \zeta^*$. Referring back to Section VI, the presence of the singular lines led to two apparent difficulties peculiar to the boundary layers studied here. First, it was not clear that the orders of integration and differentiation can be inverted as was done in evaluating the integral (6.5) from the result (6.23). Now that the behavior of $Z_+$ in $R_+$ and, by implication, of $Z_-$ in $R_-$ is seen to be satisfactory, we can justify the inversion by dividing up the interval $-1 \leq \mu \leq 1$ into three regions by separating out $R_-$ and $R_+$. In none of these three regions does the inversion present any difficulty. Second, a question arose concerning the contribution from $R_+$ and $R_-$ to $y$ via the first term on the right-hand side of equation (6.15). The contribution from $R_+$ is easily seen to be of the same order in $\nu$ as

$$\int \int \int d\psi d\xi d\psi Z_+(s-2\Omega \cos \psi)$$

i.e. as

$$\int \int \int d\psi d\xi d\psi Z_+ \psi$$

(7.15)

and, using the results (7.11) and (7.14), this integral is of order $\nu^{4/5}$. Thus we see that, although the velocities in the neighborhood of $R_+$ are larger by a factor of $\nu^{-1/10}$ than those elsewhere in the boundary layer, their contribution to $y$ is smaller by a factor of $\nu^{1/5}$. A similar remark applies to $R_-$.
The research reported in this paper was supported in part (P. H. R.) by the United States Air Force through Research Grant AF-AFOSR 62-136. We are grateful to Professor Chandrasekhar for interesting us in this problem, and for improving the presentation of our results.
