March 1977
(Received December 21, 1976)
The paper is concerned with the asymptotic behavior as \( t \to \infty \) of solutions \( u(x,t) \) of \( u_t - u_{xx} - f(u) = 0 \) \((x \in (-\infty, \infty))\) in the case 
\[ f(0) = f(1) = 0, \quad f'(0) < 0, \quad f'(1) < 0. \]

Commonly, a travelling front solution \( u = U(x - ct), \quad U(-\infty) = 0, \quad U(\infty) = 1, \) exists. The following types of global stability results for fronts and various combinations of them are given:

1. Let \( u(x,0) = u_0(x) \) satisfy \( 0 \leq u_0 \leq 1. \) Let \( a^- = \limsup_{x \to -\infty} u_0(x), \quad a^+ = \liminf_{x \to \infty} u_0(x). \) Then \( u \) approaches a translate of \( U \) uniformly in \( x \) and exponentially in time, if \( a^- \) is not too far from 0, and \( a^+ \) not too far from 1.

2. Suppose \( \int_0^1 f(u)du > 0. \) If \( a^- \) and \( a^+ \) are not too far from 0, but \( u_0 \) exceeds a certain threshold level for a sufficiently large \( x \)-interval, then \( u \) approaches a pair of diverging travelling fronts.

3. Under certain circumstances, \( u \) approaches a "stacked" combination of wave fronts, with differing ranges.

THE APPROACH OF SOLUTIONS OF NONLINEAR DIFFUSION EQUATIONS TO TRAVELLING FRONT SOLUTIONS

Paul C. Fife and J. B. McLeod

1. Introduction

This paper is concerned with the pure initial value problem for the nonlinear diffusion equation

\[ u_t - u_{xx} - f(u) = 0 \quad (-\infty < x < \infty, \ t > 0), \]

the initial value being, say,

\[ u(x,0) = \varphi(x) \quad (-\infty < x < \infty). \]

One of the central questions of interest for this problem is the behavior as \( t \to \infty \) of the solution \( u(x,t) \), and in particular one would like to determine under what circumstances it does (or does not) tend to a travelling front solution. This problem has attracted an increasing amount of attention in recent years, and some of this work is given in references [1-5, 11-17, 21, 23]. We mention in particular the classic paper of Kolmogorov, Petrovskii and Piskunov [16], the extensions by Kanel' [14, 15], and the more recent work of Aronson and Weinberger [1, 2]. These papers assume, as do we, that \( f \in C^1 \) with \( f(0) = f(1) = 0 \), so that \( u \equiv 0 \) and \( u \equiv 1 \) are particular solutions of (1.1). A travelling front is a solution of (1.1) of the form \( u = U(x - ct) \) for some \( c \) (the velocity),

Sponsored in part by the United States Army under Contract No. DAAG29-75-C-0024, in part by the National Science Foundation under Grant MPS-74-06835-A01, and in part by a Science Research Council British Research Fellowship.
with the limits $U(\pm \infty)$ existing and unequal, and for definiteness we take $U(-\infty) = 0$ and $U(+\infty) = 1$. With the above assumptions on $f$, it is a standard result that if $\varphi$ is piecewise continuous and $0 \leq \varphi(x) \leq 1$, then there exists one and only one bounded classical solution $u(x,t)$ to (1.1-2), and $0 \leq u(x,t) \leq 1$ for all $x,t$. We shall always make these assumptions on $\varphi$ and $f$, and shall be concerned only with this unique bounded solution.

A particular case of (1.1) was introduced by Fisher [9] to model the spread of advantageous genetic traits in a population. A mathematical treatment was given in [16], assuming

$$f(u) > 0 \text{ for } u \epsilon (0,1), f'(0) > 0, f'(1) < 0, f'(u) \geq f'(0).$$

It is shown there that if the initial function $\varphi$ is chosen so that

$$\varphi(x) \equiv 0 \text{ for } x < 0, \varphi(x) \equiv 1 \text{ for } x > 0,$$

then it is indeed true in a certain sense that the solution of the initial value problem "tends" to a travelling front. Specifically, there exists a travelling front $U(x - ct)$ and a function $\psi(t)$ such that, as $t \rightarrow \infty$,

$$u(x,t) - U(x - ct - \psi(t)) \rightarrow 0 \text{ uniformly in } x,$$

and $\psi'(t) \rightarrow 0$. Because it is not true that $\psi(t)$ tends to a finite limit as $t \rightarrow \infty$, $u$ does not approach a travelling front uniformly in $x$; what does happen, however, and what (1.3) implies, is that the $x$-profile of the function $u$ (monotone in $x$ for each $t$) approaches that of the travelling front $U$.

In [14], Kanel' proves similar convergence results for the case

$$f(u) \leq 0 \text{ for } u \epsilon [0, a], a < 1,$$

$$f(u) > 0 \text{ for } u \epsilon (a, 1).$$
He also assumes \( f'(l) < 0, \int_0^1 f(u)du > 0 \). This set of conditions includes the equation for combustion of certain gases, in which \( f(u) = 0 \) for \( u \in (0, \alpha) \), and also the important case in which \( f(u) < 0 \) in \((0, \alpha)\).

The latter case, when \( f \) has exactly one intermediate zero in \((0, l)\), is called the "heterozygote inferior" case by Aronson and Weinberger [1], reference being made to the genetical context envisaged by Fisher. But it is relevant in other contexts besides Fisher's. It serves to describe signal propagation along bistable transmission lines [19], and is a degenerate case of the FitzHugh-Nagumo model for the propagation of nerve pulses. See also [18]. Finally, this case is also very relevant to models recently devised by Fife in connection with pattern formation and wave propagation in a diffusing and reacting medium [6, 7]. This bistable case of Fisher's equation, and its generalizations, are the principal objects of study in the present paper.

In his paper [14], Kanel' allows \( \varphi \) to be more general than a step function (as in [16]), though he still requires it to be either monotone and \( 0 \) or \( 1 \) outside a finite interval, or a perturbation of a travelling front. The convergence statement is stronger than that in [16], in that \( \psi = \text{constant} \).

Aronson and Weinberger [1] introduce also the "heterozygote superior" case

\[
f(u) > 0 \text{ for } u \in (0, \alpha), \ f(u) < 0 \text{ in } (\alpha, 1), \ f'(0) > 0, \ f'(l) > 0 .
\]
In relation to the travelling front question, they show that in each case mentioned above, there is a number \( c^* > 0 \) with the property that every nonzero disturbance of the state \( u \equiv 0 \) which is initially confined to a half-line \( x < x_0 \) (so that \( \phi(x) = 0 \) for \( x \geq x_0 \)) and which exceeds some threshold value propagates with an asymptotic speed \( c^* \), in the following sense:

\[
\lim_{t \to \infty} u(x + ct, t) = 0 \quad \text{for each } x \text{ and each } c > c^*,
\]

and

\[
\lim_{t \to \infty} u(x + ct, t) \geq \alpha \quad \text{for each } x \text{ and each } c \quad \text{with } 0 \leq c < c^*.
\]

Rothe [21], Hoppensteadt [12], McKean [17], Stokes [23], and Kametaka [13] have recently taken another look at the case \( f(u) > 0 \) for \( u \in (0, 1) \). Stokes, taking \( \phi \) to be a step function or a sufficiently steep monotone function, improves the convergence result in [16] by showing that \( \psi = \text{constant} \) in the case \( 4f'(0) < (c^*)^2 \). Rothe, Hoppensteadt, and Kametaka show, among other things, that by prescribing the precise asymptotic (in \( x \)) behavior of \( \phi \) ahead of the front, one can obtain uniform convergence to travelling fronts. McKean applies probabilistic methods to the case \( f(u) = u(1-u) \) to obtain similar results.

Chueh [4] has treated the case when \( f \) is allowed to depend on \( u' \) and a travelling front represented by a saddle-saddle phase plane trajectory exists. He obtains convergence of the profile of \( u \) to that of the front.
Our main object in the present paper is to show that under minimal assumptions on \( \phi \), when \( f'(0) < 0, f'(1) < 0 \), the solution converges uniformly to one of various types of travelling front configurations. A later paper will present convergence results for more general functions \( f \).

Typical results obtained here for the bistable case are the following.

Let \( f \in C^1[0,1] \) satisfy, for some \( \alpha \in (0,1) \),

\[
\begin{align*}
f(u) < 0 & \quad \text{for } u \in (0,\alpha), \quad f(u) > 0 \quad \text{in } (\alpha,1), \quad f'(0) < 0, \quad f'(1) < 0.
\end{align*}
\]

By [14], there exists a unique (except for translation) monotone travelling front \( U(x - ct) \). Suppose that \( 0 \leq \phi(x) \leq 1 \) for all \( x \), with

\[
\liminf_{x \to -\infty} \phi(x) > \alpha, \quad \limsup_{x \to \infty} \phi(x) < \alpha.
\]

Then for some \( x_0 \), the solution of the initial value problem approaches \( U(x - ct - x_0) \) uniformly in \( x \) as \( t \to \infty \). Further, \( c > 0 \) according as \( \int_0^1 f(u)du < 0 \), and the rate at which the limit is approached is exponential.

On the other hand, suppose that \( \phi \) is of bounded support (or more generally, that \( \limsup_{x \to \pm \infty} \phi(x) < \alpha \), and that \( \phi(x) > \alpha + \eta \) for some \( \eta > 0 \)
and \( |x| < L \). If \( L \) is large enough, depending on \( \eta \), and \( \int_0^1 f(u)du > 0 \),

then the solution develops (uniformly in \( x \)) into a pair of diverging travelling fronts

\[
U(x - ct - x_0) + U(-x - ct - x_1) - 1.
\]
We also treat cases where \( f \) has more than one internal zero. To each triple of adjacent zeros of \( f \) with properties analogous to the zeros \((0, a, 1)\) in the heterozygote inferior case, there of course corresponds a travelling front with characteristic speed and characteristic limits at \( \pm \infty \). For simplicity consider the case of two adjacent triples of this type (thus five zeros in all), and a solution of (1.1) with range equal to the combined ranges of the two travelling fronts. Let \( c_0, c_1 \) be the two velocities, ordered by increasing \( u \). If \( c_0 < c_1 \), we can show that the solution will tend to split into two separate travelling fronts, becoming very flat for \( u \) near the center zero of the five, and that there exists no single travelling front with range from the first to the fifth zero. If \( c_0 > c_1 \), however, there exists a unique such travelling front, and this corresponds to the fact that in this case a splitting as described above would be conceptually impossible. The solution will develop into the unique travelling front. The case \( c_0 = c_1 \) is one which we are unable to discuss by the methods of the present paper.

The principal tools used throughout the paper are a priori estimates and comparison theorems for parabolic equations. It may be well to state here the particular results of this type that we shall need. The indicated Schauder estimates can be found, for example, in [10, Thm. 4 of Chapter 7, and Thm. 5 of Chapter 3], and the comparison theorems in [20] with extensions in [1].

Let \( Q \) be a rectangle \( [x_0, x_1] \times [t_0, t_1] \) in the \((x, t)\) plane with \( t_0 \geq 0 \) and with any of the \( x_0, x_1, t_1 \) either finite or infinite.
Let the sides be of length $\geq 2$. Corresponding to $Q$, let $Q'$ be the smaller rectangle $[x_0 + 1, x_1 - 1] \times [t_0 + 1, t_1]$. For a function $u$ with derivatives appearing in (1.1) defined and continuous in $Q$, let

$$
|u|_0^Q = \sup_{(x,t) \in Q} |u(x,t)|, \quad |u|_1^Q = |u|_0^Q + |u_x|_0^Q,
$$

$$
|u|_2^Q = |u|_1^Q + |u_{xx}|_0^Q + |u_t|_0^Q.
$$

**Consequences of interior Schauder estimates:** Let $u$ be a solution of (1.1) in $Q$. Then for some $C > 0$, independent of $u$ and $Q$,

$$
|u|_1^Q \leq C(\|f \circ u\|_0^Q + |u|_0^Q),
$$

$$
|u|_2^Q \leq C(\|f \circ u\|_1^Q + |u|_0^Q) \leq C(\|f \circ u\|_0^Q|u|_1^Q + |u|_0^Q),
$$

(1.6) the moduli of continuity of $u_{xx}$ and $u_t$ in $Q'$ are subject to a bound depending only on $\|f \circ u\|_1^Q$ and $|u|_0^Q$.

An immediate consequence of the above is that the uniform boundedness of $u$ in the half-space $\{t > 0\}$ implies that of $u_x, u_{xx},$ and $u_t$ in the half-space $\{t > 1\}$. We shall use this boundedness property throughout the paper without further mention.

The comparison arguments we use are quite standard. Let $N$ be the nonlinear differential operator, acting on functions of $x$ and $t$, defined by

$$
Nu = u_t - u_{xx} - cu_x - f(u).
$$
Consider the initial value problem
\begin{equation}
\text{Nu} = 0 \quad \text{for} \quad (x, t) \in (-\infty, \infty) \times (0, \infty),
\end{equation}
\begin{equation}
\text{u(x, 0) = } \psi(x).
\end{equation}

A regular subsolution \( u(x, t) \) of (1.8-9) is a function defined and continuous in \((-\infty, \infty) \times [0, T), T < \infty\), with derivatives appearing in (1.7) continuous in \((-\infty, \infty) \times (0, T), \) and satisfying
\[ \text{Nu} \leq 0 \quad \text{in} \quad (-\infty, \infty) \times (0, T), \quad u \leq \psi \quad \text{for} \quad t = 0. \]

A subsolution is defined to be a function of the form
\[ u(x, t) = \text{Max}\{u_1(x, t), \ldots, u_n(x, t)\} \]
for some set \( \{u_i\} \) of regular subsolutions with common domains.

Supersolutions are defined analogously.

**Comparison Theorem:** Let \( u \) be a subsolution, and \( \bar{u} \) a supersolution, of (1.8-9). Then \( u(x, t) \leq \bar{u}(x, t) \) in \((-\infty, \infty) \times [0, T). \)

In this theorem either \( u \) or \( \bar{u} \) could, of course, be an exact solution.

The plan of the paper is as follows. In §2, we review the existence and uniqueness of travelling front solutions, primarily for the case where \( f(u) \leq 0 \) for \( u \) sufficiently small and positive and \( f(u) \geq 0 \) for \( u \) sufficiently near 1. Many, but not all, of the results covered in this section are known and have appeared previously.

In §3, we state our precise results on uniform convergence. These are proved in §4-6.

Most of the results of the present paper were announced in [8].
2. Existence and uniqueness of travelling fronts

We assume throughout that $f \in C^1[0,1]$ and $f(0) = f(1) = 0$.

We first make the point that any travelling front with range $[0,1]$ is necessarily monotonic.

Lemma 2.1: Any solution $u = U(x - ct)$ of (1.1) with $U \in [0,1], U(-\infty) = 0, U(\infty) = 1$, necessarily satisfies $U'(z) > 0$ for finite $z = x - ct$.

Proof: Such a function $U(z)$ satisfies the ordinary differential equation

$$U'' + cU' + f(U) = 0,$$

and so corresponds to a trajectory in the $(U,P)$ phase plane of the system

$$\frac{dU}{dz} = P,$$

$$\frac{dP}{dz} = -cP - f(U)$$

connecting the stationary points $(0,0)$ and $(1,0)$. This trajectory is a simple curve, since the differential equation (2.1) is of the second order, and it has the properties that it stays in the strip $0 \leq U \leq 1$, and is directed toward the right for $P > 0$, and toward the left for $P < 0$. Any simple curve with these properties must be such that $P \geq 0$ throughout its length. If it contains a point $(U_0,0)$ with $U_0 \in (0,1)$, then there would exist a travelling front $U(z)$ such that $U(0) = U_0, U'(0) = 0$.

Then $U'(0) \neq 0$, for otherwise by uniqueness of solutions of (2.1), $U = U_0$. This means that $P$ would change sign as the point $(U_0',0)$ is crossed, which we have seen to be impossible. Therefore $P = U' > 0$ except at the endpoints. This completes the proof.
In view of Lemma 2.1, to any travelling front with range \([0, 1]\) there corresponds a function \(P(U)\) defined for \(U \in [0, 1]\), positive in \((0, 1)\), zero at \(U = 0\) or \(1\), representing the derivative \(\frac{dU}{dz}\).

From (2.1), we see that it satisfies the equation

\[
(2.4) \quad P' + \frac{f}{P} = -c
\]

or, eliminating \(c\),

\[
(2.5) \quad P'' + \left(\frac{f}{P}\right)' = 0,
\]

where \(c\) is the corresponding wave speed. Moreover \(P\) has to satisfy the boundary conditions

\[
(2.6) \quad P(0) = P(1) = 0.
\]

Conversely, given such a function \(P\) satisfying (2.4), (2.6), we may obtain a corresponding solution of (2.1) by integrating

\[
U'(z) = P(U), \quad U(0) = \frac{1}{2}.
\]

This equation may be solved for \(z\) in an interval \((z_0, z_1)\) to obtain a monotone solution with \(\lim_{z \to z_0} U(z) = 0\), \(\lim_{z \to z_1} U(z) = 1\). To show that

\[
\begin{align*}
U(x, t) = U(x - ct)
\end{align*}
\]

is a travelling front as we have defined it, we have only to verify that \(z_0 = -\infty\), \(z_1 = \infty\).

Since \(f(0) = 0\), we have that \(|f(U)| < \beta U\) for some \(\beta\). Let \(\gamma\) be a positive number such that \(\frac{\beta}{\gamma} - c < \gamma\). Let \(S\) be the line \(P = \gamma U\) in the \((U, P)\) plane. If the graph of the given solution \(P(U)\) touches \(S\)
at a point in the first quadrant distinct from the origin, then at that point, \( P' = -c - \frac{f}{P} \leq -c + \frac{\beta}{\gamma} < \gamma \), so that the trajectory immediately goes below \( S \). This implies that for some \( \delta > 0 \), either

(i) \( P(U) > \gamma U \) for \( U \in (0, \delta) \),

or (ii) \( P(U) < \gamma U \) for \( U \in (0, \delta) \).

In the former case we have, from (2.4),

\[ P'(U) = -c - \frac{f}{P} \leq -c + \frac{\beta}{\gamma} < \gamma, \quad \text{so that} \quad P(U) \leq \gamma U. \]

Therefore (ii) must hold. But then

\[ -z_0 = \int_0^{1/2} \frac{du}{P(u)} > \int_0^{1/2} \frac{du}{u} = \infty, \quad \text{so that} \quad z_0 = -\infty. \]

Similarly, \( z_1 = \infty \).

Hence if \( f \in C^1[0, 1] \), \( f(0) = f(1) = 0 \), there is a one-one correspondence between travelling fronts (modulo shifts in the independent variable \( z \)) and solutions of (2.4), (2.6), positive in \((0, 1)\).

The form of the equation (2.4) makes it clear that for every solution-pair \((P, c)\), there is a second pair \((-P, -c)\), so that our theory applies to monotone decreasing solutions of (2.1) as well.

Integration of (2.4) (after multiplication by \( P \)) yields

\[ c \int_0^1 P(u)du = -\int_0^1 f(u)du, \]

so that, for a positive solution of (2.4-6), we have

\[ (2.7) \quad c \geq 0 \quad \text{according as} \quad \int_0^1 f(u)du \leq 0. \]
Lemma 2.2 (Kanel' [14]): Let $f \in C^1[0,1]$ satisfy $f(0) = 0$ and $f(u) \leq 0$ for small positive $u$. Let $P_i(U), i = 1, 2,$ be solutions of (2.4) with corresponding speeds $c_i$. Assume $P_1(0) = 0, P_i(U) > 0$ for $U \in (0, U_0)$. Then for each $U \in (0, U_0)$,

$$P_1(U) \leq P_2(U) \text{ according as } c_1 \leq c_2.$$

Proof: From (2.4), we have

$$P_1 - P_2 - \frac{f}{P_1 P_2} (P_1 - P_2) = -(c_1 - c_2),$$

so that

$$\frac{dF(U)}{dU} = - (c_1 - c_2) \exp \int_{U_0/2}^{U} (-\frac{f(t)}{P_1(t)P_2(t)})dt,$$

where

$$F(U) = (P_1 - P_2) \exp \int_{U_0/2}^{U} (-\frac{f(t)}{P_1(t)P_2(t)})dt.$$

As $U \downarrow 0$, we have $F(U) \rightarrow 0$ since $P_1 - P_2 \rightarrow 0$ and the exponential factor is bounded as $U \downarrow 0$ because of the sign of $f$. If $c_1 = c_2$, $F(U)$, being constant, is zero, so that $P_1 \equiv P_2$. But if $c_1 > c_2$, $F$ is strictly decreasing, so that $P_1 < P_2$ for $U > 0$.

In the remainder of this section, we shall usually assume that $f$ satisfies the following conditions:
\[
\begin{aligned}
f &\in C^1[0,1], \quad \text{with } f(0) = f(1) = 0, \\
f(u) &\leq 0 \quad \text{for } u \text{ sufficiently small}, \\
f(u) &> 0 \quad \text{for } u \text{ sufficiently near } 1.
\end{aligned}
\] (2.8)

**Corollary 2.3:** Let \( f \) satisfy (2.8). Then there exists at most one solution to (2.5-6), positive in (0,1).

**Proof:** Suppose there exist two; let them be those in Lemma 2.2, wherein \( U_0 = 1 \). The fact that \( P_1(l) = P_2(l) = 0 \) implies, by that lemma, that \( c_1 = c_2 \), and in turn that \( P_1 = P_2 \).

**Theorem 2.4:** Let \( f \in C^1[0,1] \), and \( f(0) = f(1) = 0 \). For some \( \alpha \in (0,1) \), suppose that one of the following assertions holds:

(a) \( f \leq 0 \text{ in } (0,\alpha); f > 0 \text{ in } (\alpha,1); \int_0^1 f(u)du > 0; \)

(b) \( f < 0 \text{ in } (0,\alpha); f > 0 \text{ in } (\alpha,1); \int_0^1 f(u)du < 0; \)

(c) \( f < 0 \text{ in } (0,\alpha); f > 0 \text{ in } (\alpha,1). \)

Then there exists one and (by Corollary 2.3) only one solution of (2.5-6), positive in (0,1).

**Remark:** The theorem is in some sense best possible. For if we relax the restriction

\[
\int_0^1 f(u)du > 0
\]

in case (a) and consider instead

\[
\int_0^1 f(u)du = 0,
\]

-13-
with \( f = 0 \) in \((0, \beta)\), say, where \( 0 < \beta < \alpha \), then the only possible
solution is, by (2.7), a solution of (2.4) for which \( c = 0 \); and since
\( f = 0 \) in \((0, \beta)\), we have \( P = 0 \) in \((0, \beta)\), which shows a positive
solution to be impossible.

**Proof:** This theorem (in case (a)) was proved in [14], [1, Thm. 4.2] and
[2, Thm. 4.1]. Case (b) follows from case (a) by replacing \( U \) by \( 1 - U \),
and \( f \) by \(-f\). Case (c) for \( c \neq 0 \) follows from the other two cases.

For \( c = 0 \), (2.4) can be integrated, and the result is the required solution.

Our object now is to extend this existence theorem to a wider class of
functions \( f \), still retaining the hypothesis (2.8). At the same time, we
shall consider the possibility of solutions of (2.4) with internal zeros, which
represent phase-plane images of "stacked" combinations of travelling fronts.

The following preliminary lemmas will be needed.

**Lemma 2.5:** Let \( f \in C^1[0,1] \) with \( f(0) = 0 \), \( f(1) = 0 \), and let
there exist a solution \( P_0(U) \) of (2.4), positive on \((0, \alpha)\),
with \( P_0(0) = 0 \) and "velocity" \( c = c_0 \). Then for any \( c \leq c_0 \),
there exists a solution \( P(U) \) of (2.4) on \((0, \alpha)\) with \( P(0) = 0 \) and
\( P(U) > P_0(U) \). There exists a maximal such solution, which we denote by
\( P_c(U) \), so that for any other solution \( \tilde{P} \) with the given \( c \) satisfying
\( \tilde{P}(0) = 0 \), and for \( U \) in the domain of \( \tilde{P} \), we have \( P_c(U) \geq \tilde{P}(U) \).

Moreover, \( P_c(U) \) depends continuously on \( c \) for \( c \leq c_0 \).

**Proof:** We follow the construction used in [2]. For \( \nu > 0 \), \( c \leq c_0 \), let
\( P_{c, \nu}(U) \) be the solution of the regular initial value problem
Clearly \( P_c, \nu(U) > P_0(U) \) for \( U \in [0, \alpha] \). Since \( P_{c, \nu}(U) \) is monotone in \( \nu \), \( P_c(U) = \lim_{\nu \to 0} P_{c, \nu}(U) \) exists and satisfies \( P_c(U) \geq P_0(U) \).

Furthermore, by the monotone convergence theorem, \( P_c \) satisfies (2.4), and so is the required solution. If \( \tilde{P}_c \) is another solution, clearly \( P_{c, \nu} \geq \tilde{P}_c \) for all \( U \) where the latter is defined, and so passing to the limit, we obtain that \( P_c \) is maximal. Its continuous dependence on \( c \) is proved as in [2, Prop. 4.5].

In the following when we speak of a "travelling front over \([\alpha, \beta]\) with velocity \( c'\)" we shall mean a solution of (2.4) with the given \( c \), positive in \((\alpha, \beta)\) and vanishing at \( \alpha \) and \( \beta \).

**Lemma 2.6:** Let \( f \) satisfy (2.8). For \( 0 < \alpha \leq \beta < 1 \), assume that there exist travelling fronts over \([0, 1] \), \([0, \alpha] \), and \([\beta, 1] \), with velocities \( c_{01}, c_{0\alpha}, \) and \( c_{\beta 1} \) respectively. Then necessarily

\[
(2.9) \quad c_{0\alpha} > c_{01} > c_{\beta 1}.
\]

**Proof:** We apply Lemma 2.2 with \( P_1 \) the solution over \([0, 1]\), \( P_2 \) the solution over \([0, \alpha]\), and \( U_0 = \alpha \). Since \( P_2(\alpha) = 0 < P_1(0) \), we have that \( c_{01} = c_1 < c_2 = c_{0\alpha} \). The other inequality in (2.9) is proved in a similar fashion.

**Theorem 2.7:** Let \( f \in C^1[0, 1] \) with \( f(0) = f(1) = 0 \), and let there exist a travelling front over \([0, \alpha]\) with velocity \( c_{0\alpha} \), and one over \([\alpha, 1]\) with velocity \( c_{\alpha 1} < c_{0\alpha} \). Then there exists a travelling front over \([0, 1]\) with velocity \( c_{01} \) satisfying

\[
(2.10) \quad c_{0\alpha} > c_{01} > c_{\alpha 1}.
\]
Remark: For this theorem to hold, it is not necessary that \( f \) satisfy (2.8). But if it does, then Lemma 2.6 shows the inequality \( c_{a1} < c_{0\alpha} \) to be a necessary as well as a sufficient condition for the existence of a travelling front over \( [0,1] \).

Proof: For all \( c < c_{0\alpha} \), let \( P_{c}(U) \) be the (maximal) solution of (2.4) guaranteed by Lemma 2.5, and let \( g(c) = P_{c}(a) \), \( c < c_{0\alpha} \). It is continuous in \( c \), and satisfies \( \lim_{c \uparrow c_{0\alpha}} g(c) = 0 \).

By the symmetrical argument, for each \( c > c_{a1} \), there is a positive solution \( \bar{P}_{c}(U) \) of (2.4) satisfying \( \bar{P}_{c}(1) = 0 \), with \( h(c) = \bar{P}_{c}(a) \) continuous, and \( \lim_{c \downarrow c_{a1}} h(c) = 0 \). Hence there is a solution \( c = c_{0l} \) of \( g(c) = h(c) \). For this value of \( c \), \( \bar{P}_{c} \) is the continuation of \( P_{c} \), which is therefore the required travelling front over \( [0,1] \).

Definition: A closed interval \( I \subset [0,1] \) is called admissible if \( f \) vanishes at the endpoints, \( f \leq 0 \) near the left endpoint, \( f \geq 0 \) near the right endpoint, and there exists a travelling front over \( I \).

Suppose we have given a decomposition of \( [0,1] \) into nonoverlapping adjacent admissible intervals \( [0,1] = \bigcup_{j=1}^{m} I_{j} \), ordered from left to right (so that the right endpoint of \( I_{j} \) is the left endpoint of \( I_{j+1} \)). Let \( \{c_{j}\} \) be the associated velocities of the travelling fronts over the \( I_{j} \).

Definition: Such a decomposition is called minimal if \( c_{j} \) is nondecreasing in \( j \): \( c_{j+1} \geq c_{j} \).
Theorem 2.8: If there exists a decomposition of $[0, 1]$ into admissible
intervals, then there exists a unique minimal decomposition.

Remark: The significance of minimal decompositions will be seen in Theorem 3.3
and in a later paper. In fact, monotone solutions of (1.1) with range $[0, 1]$ will
split into a "stack" of travelling fronts, each with range in one of the
intervals of the minimal decomposition and with its distinctive
asymptotic speed, and (at least when the $c_j$ are distinct) spreading
away from each other.

Proof: The existence of a minimal decomposition is trivial. In fact, if
the original decomposition is not minimal, there will be two adjacent
intervals $I_1$ and $I_2$, say, with associated-velocities satisfying $c_1 > c_2$.
By Theorem 2.7, we may combine them into a single admissible interval.
Thus proceeding in a finite number of steps (since each step reduces by one
the total number of intervals), we arrive at a minimal decomposition.

We now show that there cannot be two distinct minimal decomposi-
tions. Let two minimal decompositions be given. If they are distinct,
there will be an interval of one, call it $I$, which overlaps at least two
intervals of the other. Call the latter overlapping intervals $I_1, \ldots, I_q$,
ordered from left to right, so that $I \subset \bigcup_{k=1}^{q} I_k$ and $I \cap I_k \neq \emptyset$, $1 \leq k \leq q$.
The interval $I \cap J_1$, being a union of the original intervals, has a
minimal decomposition $I \cap J_1 = \bigcup_{k=1}^{n} I_k'$, again ordering from left to right.
Let the velocities associated with $I, I_k$, and $I_k'$ be $c, d_k$, and $c_k$.
respectively. By Lemma 2.6, \( c'_1 > c \) and \( c'_n \leq d_1 \). By minimality, \( c'_1 \leq c'_n \). Hence \( c < d_1 \). A similar argument shows that \( c > d_q \). Hence \( d_1 > d_q \). But this contradicts the minimality of the second decomposition, and proves the theorem.
3. Uniform convergence results

Beginning with this section, we take up the question of the asymptotic behavior as $t \to \infty$ of solutions of the initial value problem (1.1-2). We deal with circumstances under which a solution approaches a travelling front, or a combination of fronts, uniformly in $x$ and exponentially in $t$ as $t \to \infty$. Conclusions to this effect, under minimal assumptions on $\varphi$, can be made when the travelling front or fronts concerned are over $u$-intervals at the endpoints of which $f'(u) < 0$. The basic result is the following.

**Theorem 3.1:** Let $f \in C^1[0,1]$ satisfy $f(0) = f(1) = 0$, $f'(0) < 0$, $f'(1) < 0$, $f(u) < 0$ for $0 < u < \alpha_0$, $f(u) > 0$ for $\alpha_1 < u < 1$, where $0 < \alpha_0 \leq \alpha_1 < 1$.

Assume there exists a travelling front solution $U$ of (1.1) with speed $c$.

Let $\varphi$ satisfy $0 \leq \varphi \leq 1$, and

$$\limsup_{x \to -\infty} \varphi(x) < \alpha_0, \liminf_{x \to \infty} \varphi(x) > \alpha_1.$$  

Then for some constants $z_0$, $K$, and $\omega$, the last two positive, the solution $u(x,t)$ of (1.1-2) satisfies

$$|u(x,t) - U(x - ct - z_0)| < Ke^{-\omega t}.$$ 

**Remark:** It is clear from §2 that the existence of a travelling front is by no means guaranteed. However, in that section readily verifiable conditions on $f$ were given which ensure its existence. If $f$ satisfies these conditions, the existence assumption in the statement of Theorem 3.1
may of course be omitted. A particularly important case is that of the
degenerate Nagumo's equation, in which \( a_0 = a_1 \). A travelling front does
exist in this case.

Theorem 3.1 implies that a solution which vaguely resembles a
front at some initial time will develop uniformly into such a front as \( t \to \infty \).
"Vaguely resembles" simply means that the solution is less than \( a_0 \)
far to the left, and greater than \( a_1 \) far to the right. Of course, if the
words "left" and "right" are interchanged in this statement, the same
conclusion holds; the front will then face right rather than left, and will
travel in the opposite direction.

There are also situations in which the solution will develop into
a pair of such fronts, moving in opposite directions. That is the gist of the
following result.

**Theorem 3.2:** Let \( f \) satisfy the hypotheses of Theorem 3.1, and in
addition

\[
(3.3) \quad \int_0^1 f(u)\,du > 0.
\]

Let \( \varphi \) satisfy \( 0 \leq \varphi \leq 1 \), and

\[
(3.4) \quad \limsup_{|x| \to \infty} \varphi(x) < a_0, \quad \varphi(x) > a_1 + \eta \quad \text{for} \quad |x| < L,
\]

where \( \eta \) and \( L \) are some positive numbers. Then if \( L \) is sufficiently
large (depending on \( \eta \) and \( f \)), we have for some constants \( x_0, x_1, K, \)
and \( \omega \) (the last two positive),

-20-
Note that (3.3) implies \( c < 0 \). The intuitive meaning of (3.5) is that the \( x \)-interval on which \( u \) is near the value 1 is finite and is elongating in both directions, with speed \( |c| \). If the inequality in (3.3) is reversed, and appropriate changes in (3.4) are made, then an analogous convergence result is still obtained. In the latter case, the interval on which \( u \) is near 0 will elongate.

Finally, we consider the possibility of the solution developing into a combination of fronts with different, but adjacent, ranges. As in § 2, we call them a stacked combination of fronts, and for simplicity treat only the case when there are two of them.

**Theorem 3.3:** Let \( f(u_i) = 0 \) and \( f'(u_i) < 0 \), \( i = 1, 2, 3 \), where \( u_1 < u_2 < u_3 \). Let there exist travelling fronts \( U_1(x - c_1t) \) and \( U_2(x - c_2t) \) with ranges \( (u_1, u_2) \) and \( (u_2, u_3) \) respectively. Assume \( c_1 < c_2 \).

Let \( \alpha_1 \) be the least zero of \( f \) greater than \( u_1 \), and \( \alpha_2 \) the greatest zero less than \( u_3 \). Suppose \( u_1 < \varphi(x) < u_3 \), and

\[
\limsup_{x \to -\infty} \varphi(x) < \alpha_1, \quad \liminf_{x \to \infty} \varphi(x) > \alpha_2.
\]

Then there exist constants \( x_1, x_2, K, \) and \( \omega \), the last two positive, such that

\[
|u(x, t) - U_1(x - c_1t - x_1) - U_2(x - c_2t - x_2) + u_2| < Ke^{-\omega t}.
\]
Note that (3.7) implies, in particular, that

$$\lim_{t \to \infty} u(\beta t, t) = \begin{cases} 
    u_1 & \text{for } \beta < c_1, \\
    u_2 & \text{for } c_1 < \beta < c_2, \\
    u_3 & \text{for } c_2 < \beta.
\end{cases}$$
4. Proof of Theorem 3.1 (Beginning)

In this section we establish the uniform convergence of
\[ u(x, t) - U(x - ct - z_0) \] to zero as \( t \to \infty \), the exponential nature of
this convergence being deferred to section 5.

Several lemmas will be needed in the proofs of the theorems given
in the previous section. Some arguments are easiest to give in terms
of a moving coordinate system. For purposes of Theorem 3.1, we set
\( z = x - ct \), and write the solution of (1.1-2) as
\[ v(z, t) = u(x, t) = u(z + ct, t) . \]
Our basic lemma in the following.

**Lemma 4.1:** Under the assumptions of Theorem 3.1, there exist constants
\( z_1, z_2, q_0, \) and \( \mu \) (the last two positive), such that
\[
(4.1) \quad U(z - z_1) - q_0 e^{-\mu t} \leq v(z, t) \leq U(z - z_2) + q_0 e^{-\mu t} .
\]

**Proof:** We prove only the left-hand inequality; the other is similar. The
function \( v \) satisfies
\[
(4.2a) \quad N[v] = v_t - v_{zz} - c v_z - f(v) = 0, \quad z \in (-\infty, \infty), \quad t > 0 ,
\]
(4.2b) \[
 v(z, 0) = \varphi(z) .
\]
Functions \( \xi(t) \) and \( q(t) \) \( (q(t) \) positive) will be chosen so that
\[ v(z, t) = \text{Max}[0, U(z - \xi(t)) - q(t)] \]
will be a subsolution.

First, let \( q_0 > 0 \) be any number such that \( \alpha_1 < 1 - q_0 < \liminf_{z \to \infty} \varphi(z) . \)

Then take \( z^* \) so that \( U(z - z^*) - q_0 \leq \varphi(z) \) for all \( z \). This is possible,
for sufficiently large positive $z$, by virtue of (3.1). Let

$$\varphi(u,q) = \begin{cases} \frac{f(u-q) - f(u)}{q}, & q > 0, \\ -f'(u), & q = 0. \end{cases}$$

Then $\varphi$ is continuous for $q \geq 0$, and for $0 < q \leq q_0$ we have

$$a_1 < 1 - q_0 \leq 1 - q < 1,$$

so that $\varphi(l, q) > 0$. Also $\varphi(l, 0) = -f'(l) > 0$.

Thus for some $\mu > 0$, we have $\varphi(l, q) \geq 2\mu$ for $0 \leq q \leq q_0$. By continuity, there exists a $\delta > 0$ such that $\varphi(u, q) \geq \mu$ for $1 - \delta \leq u \leq 1$, $0 \leq q \leq q_0$. In this range, we have

$$f(u-q) - f(u) \geq \mu q.$$ 

Setting $\xi = z - \xi(t)$, and using the fact that

$$(4.3) \quad U'' + cU' + f(U) = 0,$$ 

we find that, if $v > 0$,

$$N[v] = -\xi'(t)U'(\xi) - cU'(\xi) - q'(t) - U''(\xi) - f(U - q)$$

$$= -\xi'(t)U'(\xi) - q'(t) + f(U) - f(U - q).$$

Thus when $U \in [1 - \delta, 1]$, $q \in [0, q_0]$,

$$N[v] \leq -\xi'U' - q' - \mu q \leq -(q' + \mu q),$$

provided $\xi' \geq 0$, since $U' \geq 0$ (see Lemma 2.1). We choose $q(t) = q_0 e^{-\mu t}$, which results in $N[v] \leq 0$ when $1 - \delta \leq U \leq 1$.

By possibly further reducing the size of $\mu$ and $\delta$ and using the same arguments, we may be assured that $N[v] \leq 0$ whenever $0 \leq U \leq \delta$, $U \geq q_0$ as well.

Now consider the intermediate values, $\delta \leq U \leq 1 - \delta$. In this range we know that $U'(z) \geq \beta$ for some $\beta > 0$. This fact was shown in Lemma 2.1.
Also, by the differentiability of \( f \), we have that \( f(U) - f(U - q) \leq \kappa q \) for some \( \kappa > 0 \). Thus

\[
N[v] \leq -\beta \xi' - q' + \kappa q.
\]

We now set

\[
\xi'(t) = (-q' + \kappa q)/\beta = (\mu + \kappa)q/\beta > 0, \quad \text{with} \quad \xi(0) = z^*.
\]

(Specifically,

(4.4a) \[ \xi = z_1 + z_2 e^{-\mu t}, \]

where

(4.4b) \[ z_2 = -q_0(\mu + \kappa)/\mu \beta, \quad z_1 = z^* - z_2. \]

Thus \( \xi(t) \) is increasing and approaches a finite limit as \( t \to \infty \). Then

\( N[v] \leq 0 \) whenever \( v > 0 \), and by our condition on \( z^* \), \( v \) will be a subsolution. Thus

\[
v(z, t) \geq v(z, t) \geq U(z - z_1) - q(t) = U(z - z_1) - q_0 e^{-\mu t},
\]

which completes the proof.

Lemma 4.2: Under the assumptions of Theorem 3.1, there exists a function \( \omega(\epsilon) \), defined for small positive \( \epsilon \), such that \( \lim_{\epsilon \to 0} \omega(\epsilon) = 0 \), and such that, if \( 0 < \phi < 1 \) and \( |\phi(z) - U(z - z_0)| < \epsilon \) for some \( z_0 \), then

\[
|v(z, t) - U(z - z_0)| < \omega(\epsilon)
\]

for all \( z \) and all \( t > 0 \).

Proof: In the proof of Lemma 4.1, we may take \( q_0 = O(\epsilon) \) and

\[
|z^* - z_0| = O(\epsilon). \quad \text{Hence also} \quad |z_1 - z_0| = O(\epsilon), \quad |z_2 - z_0| = O(\epsilon), \quad \text{and}
\]

the conclusion follows from that of the lemma.
Remark: Lemma 4.2 already yields the stability of travelling fronts in the \( C^0 \) norm. But Theorem 3.1 claims much more.

In the following development, it will be necessary to have asymptotic estimates for the derivatives of \( v \).

**Lemma 4.3:** Under the assumptions of Theorem 3.1, there exist positive constants \( \sigma, \mu, \) and \( C \) with \( \sigma > |c|/2 \), such that

\[
\begin{align*}
(4.5a) \quad & |v(z,t)|, |v_z(z,t)|, |v_{zz}(z,t)|, |v_t(z,t)| < C(e^{(-\frac{1}{2}C-\sigma)z+\mu t}), \quad z > 0; \\
(4.5b) \quad & |v(z,t)|, |v_z(z,t)|, |v_{zz}(z,t)|, |v_t(z,t)| < C(e^{(-\frac{1}{2}C+\sigma)z+\mu t}), \quad z < 0.
\end{align*}
\]

**Proof:** The wave front \( U(z) \) approaches its limits exponentially; this is easily seen by linearizing (2.1) about the constant states \( U = 0 \) and \( U = 1 \). In fact, this analysis shows that \( U(z) \to 1 \) as \( z \to \infty \) at the approximate rate \( \exp\left\{ -\frac{1}{2} \sqrt{C^2 - 4\mu^2} \right\} z \}, \) and so at an exponential rate faster than \( \exp\left\{ (-\frac{1}{2}C - \frac{1}{2}|C|)z \right\}. \) A similar analysis holds as \( z \to -\infty \).

This, together with (4.1), establishes (4.5) for the undifferentiated function \( v \). Since \( |f(u)| < k |u| \) for \( u \) near 0 and \( |f(u)| < k(1 - u) \) for \( u \) near 1, we also have that \( |f(v(z,t))| \leq C(e^{-\frac{1}{2}Cz-\sigma |z|} + e^{-\mu t}) \) for some \( C > 0 \). From this and (1.4) it follows that (4.5) is satisfied for \( v_z \).

The same estimates for \( v_{zz} \) follow then from (1.5), and (4.2a) yields them for \( v_t \). This completes the proof.

**Lemma 4.4:** For each \( \delta > 0 \), the "orbit" set

\[ \{v(\cdot, t) : t \geq \delta \}, \]

considered as a subset of \( C^2(-\infty, \infty) \), is relatively compact.
Proof: We know from (1.4-6) that \( v, v_z, \) and \( v_{zz} \) are bounded and equicontinuous for \( t \geq \delta \). Let \( \{t_n'\} \) be a given sequence. If there is a finite accumulation point \( t_\infty \), then the (uniform) continuity of \( v \) and its derivatives implies that \( v(\cdot, t) \) approaches the limit \( v(\cdot, t_\infty) \) "along a subsequence". So assume there is none. For any \( K > 0 \), let \( v_K(z, t) \) be the restriction of \( v \) to the set \( |z| \leq K, t \geq \delta \). By the Arzela theorem, for each \( K = 1, 2, \ldots \), there is a subsequence \( \{t_{n, K}\} \) such that the sequence \( \{v_K(z, t_{n, K})\} \) converges in \( C^2[-K, K] \). We may always, in fact, choose \( \{t_{n, K+1}\} \) to be a subsequence of \( \{t_{n, K}\} \). We then take a diagonal sequence, denoted by \( \{t_n\} \), so that \( \{v(z, t_n)\} \) converges uniformly on each interval \( [-K, K] \) to a limit \( w(z) \), the derivatives to order two converging to those of \( w \).

Since \( v \) satisfies (4.5), we pass to the limit as \( t \to \infty \) to obtain that \( w \) satisfies (4.5) with \( t = \infty \).

Given any \( \varepsilon > 0 \), one may choose \( T \) and \( K \) so that

\[
|\frac{\partial^k}{\partial z^k}(v(z, t) - w(z))| < \varepsilon, \ k = 0, 1, 2, \text{ for } |z| > K, t > T.
\]

This is possible by Lemma 4.3. One may also choose \( N \) so that \( t_N > T \) and

\[
|\frac{\partial^k}{\partial z^k}(v(z, t_n) - w(z))| < \varepsilon \text{ for } n > N, \ |z| \leq K.
\]

This proves that

\[
\lim_{n \to \infty} v(z, t_n) = w(z) \text{ in } C^2(-\infty, \infty), \text{ and completes the proof of the lemma.}
\]

Lemma 4.5: Under the assumptions of Theorem 3.1, there exists a value \( z_0 \) such that

\[
\lim_{t \to \infty} |v(z, t) - U(z - z_0)| = 0,
\]

uniformly in \( z \).
Proof: Let $\epsilon > 0$ be a number satisfying $|c|\epsilon < 2\mu$, where $\mu$ is the constant in Lemma 4.3. Let $w$ be a truncation of $v$ in the following sense:

$$w(z, t) = v(z, t) \text{ for } |z| \leq \epsilon t,$$
$$w(z, t) = 0 \text{ for } z \leq -\epsilon t - 1,$$
$$w(z, t) = 1 \text{ for } z \geq \epsilon t + 1,$$

and $w$ satisfies (4.5). It is clear from (4.5) that $v$ may be smoothed off in this manner so that the truncation $w$ also satisfies (4.5).

We define the Lyapunov functional

$$V[w] = \int_{-\infty}^{\infty} e^{cz} \left[ \frac{1}{2} w^2 - F(w) + H(z)F(l) \right] dz,$$

where $H(z)$ is the Heaviside step function, and $F(v) = \int_{0}^{v} f(s) ds$. It clearly converges, as do the integrals below, because of the truncation.

In fact, $V[w]$ is bounded independently of $t$. To see this, we use (4.5) to estimate it as follows:

$$|V[w]| \leq C_1 \int_{-\epsilon t - 1}^{\epsilon t + 1} e^{cz} (e^{-cz} - 2\sigma |z| + e^{-2\mu t}) dz$$

$$\leq C_2 \int_{0}^{\epsilon t} (e^{-2\sigma |z|} + e^{c|z| - 2\mu t}) dz.$$

Since $|c|\epsilon - 2\mu < 0$, the right side is bounded for all time.
Setting $V(t) = V[w(\cdot, t)]$, we have, by integration by parts,

$$\frac{\Delta V(t)}{\Delta t} = \frac{V(t + \Delta t) - V(t)}{\Delta t} = -\int_{-\infty}^{\infty} \left[ \frac{cz w_z(z, t) + w_z(z, t + \Delta t)}{z} \right] \frac{\Delta w}{\Delta t} + \frac{\Delta F(w)}{\Delta t} dz .$$

Passing to the limit as $\Delta t \to 0$ and using the uniform (in $t$) convergence of the integral, we obtain that $\dot{V}(t) = \frac{dV}{dt}$ exists, and

$$\dot{V}(t) = -\int_{-\infty}^{\infty} e^{cz}(w_{zz} + cz w_z + f(w))w_t dz .$$

Letting $Q[w] = \int_{-\infty}^{\infty} e^{cz} [w_{zz} + cz w_z + f(w)]^2 dz$, we calculate

$$\dot{V}(t) + Q[w](t) = -\int_{-\infty}^{\infty} e^{cz} [w_{zz} + cz w_z + f(w)] N[w] dz ,$$

where $N$ is given by (4.2a). Since $N[w] \geq 0$ for $|z| \leq \varepsilon t$ and $w$ satisfies (4.5),

$$|\dot{V}(t) + Q[w](t)| \leq C_1 \int_{-\varepsilon t}^{\varepsilon t} e^{cz} (e^{\frac{1}{2}c\varepsilon z} + e^{-\mu t})^2 dz$$

$$\leq C_2 (e^{-2\varepsilon t} + e^{\varepsilon |c|-2\mu t}) .$$

Again, since $\varepsilon |c| - 2\mu < 0$, we obtain

$$\lim_{t \to \infty} |\dot{V}(t) + Q[w](t)| = 0 .$$

(4.6)

Since $Q[w] \geq 0$, it follows in particular that $\limsup_{t \to \infty} \dot{V}(t) \leq 0$. We deduce the existence of a sequence $\{t_n\}$ with $t_n \to \infty$ such that

$$\lim_{n \to \infty} \dot{V}(t_n) = 0 ;$$

(4.7)

for otherwise $\limsup_{t \to \infty} \dot{V}(t) < 0$, implying that $V(t) \to -\infty$, whereas we
know from above that $V(t)$ is bounded. Combining (4.6) and (4.7), we obtain

\[
\lim_{n \to \infty} Q[w(t_n)] = 0.
\]

By Lemma 4.4, there is a subsequence of \{t_n\}, call it \{t'_n\}, along which $v(\cdot, t'_n)$, and hence $w(\cdot, t'_n)$, converges in the norm of $C^2(-\infty, \infty)$ to a limit function $\tilde{v}(z)$. From this and (4.8), we obtain, for any finite interval $I$, that

\[
\int I e^{-cz} (w_{zz} + cw_z + f(w))^2 dz \to \int I e^{-cz} (\tilde{v}_{zz} + c\tilde{v}_z + f(\tilde{v}))^2 dz = 0,
\]

and so $\tilde{v}_{zz} + c\tilde{v}_z + f(\tilde{v}) = 0$.

We also have $\tilde{v}(\infty) = 0$, $\tilde{v}(\infty) = 1$, and so by the uniqueness of travelling fronts (Corollary 2.3), we have $\tilde{v}(z) = U(z - z_0)$ for some $z_0$. This establishes that $v(z, t_n)$ approaches $U(z - z_0)$ in the sense of $C^2$ as $n \to \infty$.

To finish the proof of Lemma 4.5, we now merely apply Lemma 4.2, which indicates that once $v$ is close to $U(z - z_0)$ for some $t_n$, it remains close for all later time.
5. Proof of Theorem 3.1 (Conclusion)

Lemma 4.5 asserts the convergence of $v$ to a travelling front; we now show that the rate is exponential. This conclusion can be obtained by appealing directly to a theorem of Sattinger [22], the conditions of which are satisfied by virtue of Lemma 4.5. We give, however, an alternative proof which is in some ways simpler than Sattinger's, though more limited in scope.

Recalling the definition of $w(z, t)$ in the proof of Lemma 4.5, we set

$$h(z, t) = w(z, t) - U(z - z_0 - \alpha(t)),$$

where $z_0$ is the constant in that lemma, and $\alpha(t)$ is chosen so that for large $t$, $h$ is orthogonal to $e^{cz}U'$, i.e.,

$$\int_{-\infty}^{\infty} e^{cz}h(z, t) U'(z - z_0 - \alpha(t))dz = 0.$$  

(5.1)

The existence of such an $\alpha$, with $\alpha(\infty) = 0$, follows from the implicit function theorem. In fact, by Lemma 4.5 and estimates (4.5) (which also hold for $w, U,$ and $h$), the left side of (5.1) vanishes at $\alpha = 0, t = \infty$. Furthermore its derivative with respect to $\alpha$ is

$$\int_{-\infty}^{\infty} e^{cz}U'(z - z_0 - \alpha)dz - \int_{-\infty}^{\infty} e^{cz}h(z, t) U''(z - z_0 - \alpha)dz,$$

which is nonzero at $\alpha = 0, t = \infty$, because the right-hand integral then vanishes. The implicit function theorem also yields that $\alpha$ is continuously differentiable.
Theorem 3.1 will be proved by showing

(i) \(|h(z, t)| < Ce^{-\nu t}\), and

(ii) \(|a(t)| < Ce^{-\nu t}\).

This will imply that \(w\) converges exponentially to \(U(z - z_0)\). But we know from (4, 5) and the definition of \(w\) that

\[ |v(z, t) - w(z, t)| < Ce^{-\nu t} \]

for some (possibly different) positive \(\nu\). We shall thus obtain that \(v\) converges exponentially to \(U(z - z_0)\), as desired.

To establish (i), we work with a diffusion equation for \(h\). First we note, by the definition of \(w\), that \(w = v\) for \(|z| < \varepsilon t\), and that \(w\) and its derivatives satisfy (4, 5). We therefore have that

\[ w_t = w_{zz} + cw_z + f(w) + 0(r) , \]

where

\[ r(z, t) = \begin{cases} 0 & , \ |z| < \varepsilon t , \\ e^{-\frac{1}{2}cz - \sigma \varepsilon t} + e^{-\mu t} , & \varepsilon t \leq |z| \leq \varepsilon t + 1 , \\ 0 & , \ |z| > \varepsilon t + 1 . \] 

Therefore

\[ h_t = w_t + a'u' = w_{zz} + cw_z + f(w) - U'' - cu' - f(U) + a'u' + 0(r) \]

\[ = h_{zz} + ch_z + f'(U)h + a'U' + 0(h^2) + 0(r) . \]

Setting \( h = e^{-\frac{1}{2}cz}, \) we have

\[ y_t = y_{zz} - \left(\frac{1}{4} c^2 - f'(U)\right)y + a'e^{-\frac{1}{2}cz}U' + 0(hy) + 0(e^{\frac{1}{2}cz}r) . \]

The linear operator \( L \) given by
\[ Ly = -y_{zz} + \left( \frac{1}{4} c^2 - f'(U) \right)y , \]

with appropriate domain in \( L^2(-\infty, \infty) \), is self-adjoint with a continuous spectrum to the right of \( \text{Min}\left\{ \frac{1}{4} c^2 - f'(0), \frac{1}{4} c^2 - f'(1) \right\} \), which is strictly positive, and a discrete spectrum to the left. Furthermore, we know by differentiating (2.1) that the eigenvalue \( 0 \) lies in this discrete spectrum with eigenfunction \( e^{\frac{1}{2}cz}u' \), and since this eigenfunction is of constant sign, \( 0 \) must be simple and the least eigenvalue, with all other eigenvalues strictly positive. Let \( \| \cdot \| \) denote the norm in \( L^2(-\infty, \infty) \). We know that \( e^{\frac{1}{2}cz}h = y \) lies in this space.

Multiplying (5.2) by \( y \) and integrating over \(( -\infty, \infty) \), we obtain, by virtue of (5.1), that

\[
\frac{1}{2} \frac{d}{dt} \| y \|^2 = (-Ly, y) + O(\| y \|^2) + O(\| e^{\frac{1}{2}cz}r \| \| y \|) .
\]

Now since \( y \) is orthogonal to the eigenfunction \( e^{\frac{1}{2}cz}u' \), corresponding to the zero eigenvalue of \( L \), the right side will in turn be

\[
\leq -M \| y \|^2 + C(\sup_z |h(z,t)| \| y \|^2 + e^{-\varepsilon t} \| y \| + e^{Cz} \| y \|) ,
\]

with \( M > 0 \) independent of \( t \). Since \( h \to 0 \) uniformly as \( t \to \infty \) and \( 2\mu > |c| \varepsilon \), we have, finally, that

\[
\frac{1}{2} \frac{d}{dt} \| y \|^2 \leq -\frac{M}{2} \| y \|^2 + O(e^{-Kt})
\]

for large enough \( t \) and some \( K > 0 \). Integration of this inequality shows that

\[
(5.3) \quad \| y \| \leq Ce^{-\nu t}
\]

for some \( \nu > 0 \).
At this point we need an interpolation lemma. Though somewhat
standard, its proof will be given later for completeness.

Lemma 5.1: Let $f \in C^1(\mathbb{R})$, and denote $f_0 = \|f\|_{C^0}$, $f_1 = \|f\|_{C^1}$. Then

$$f_0 \leq \left(\frac{3}{2}\right)^{1/3} f_1^{1/3} \left(\int_{-\infty}^{\infty} f^2(x)dx\right)^{1/3}.$$

We apply this to the function $y(\cdot, t)$. Since $\|y(\cdot, t)\|_{C^1}$ is bounded independently of $t$, estimate (5.3), and the above lemma, imply

$$\|y(\cdot, t)\|_{C^0} = O(e^{-\nu t}).$$

For each $\delta > 0$, we have from (5.4) and the definition of $y$ that

$$|h(z, t)| < Ce^{(\frac{1}{2}|c|\delta - \nu)t}$$

for $|z| < \delta t$. Let $\delta$ be such that $\frac{1}{2}|c|\delta - \nu < 0$. For $|z| > \delta t$, however, (4.5) yields that

$$|h(z, t)| < Ce^{-\nu t}, \nu > 0.$$

Therefore (5.5) holds, in fact, for all $z$ and all $t > 0$.

The proof of Theorem 3.1 will be complete if we can merely show that

$$|\alpha(t)| = O(e^{-\nu t}).$$

For this purpose we multiply (5.2) by $e^{\frac{1}{2}czU'}$ and integrate over $(-\infty, \infty)$ (the integrals converging because of the asymptotic behavior of $U'$). Thus

$$\left(e^{\frac{1}{2}czU'}, y_t\right) = -\left(e^{\frac{1}{2}czU'}, Ly\right) + \alpha'(e^{czU'}, U')$$

$$+ O((U', y^2)) + O(\|e^{\frac{1}{2}czr}\|_\infty \|e^{\frac{1}{2}czU'}\|).$$

Differentiating
\((e^{\frac{1}{2}czU'}, y) = 0\),

we have

\((e^{\frac{1}{2}czU'}, y_t) = \gamma'(e^{\frac{1}{2}czU''}, y)\),

and the scalar product on the right is seen to decay exponentially by use of the Cauchy-Schwarz inequality and (5.3). Also

\((e^{\frac{1}{2}czU'}, Ly) = (L(e^{\frac{1}{2}czU'}), y) = 0\),

and the remainder terms in (5.6) also decay exponentially. We can therefore conclude from (5.6) that

\[\gamma' = 0(e^{-\nu t}),\]

and so \(\gamma = 0(e^{-\nu t})\). This completes the proof of Theorem 3.1.

**Proof of Lemma 5.1:** Given \(\delta > 0\), let \(x_0\) be such that \(|f(x_0)| \geq f_0 - \delta\).

There is no loss of generality in supposing \(f(x_0) > 0\), so that \(f(x_0) \geq f_0 - \delta\). Then

\[f(x) = f(x_0) + \int_{x_0}^{x} f'(\bar{x})d\bar{x} \geq f_0 - \delta - |x - x_0| f_1 ,\]

for \(|x - x_0| \leq (f_0 - \delta)/f_1 \equiv t\). Thus

\[\int_{-\infty}^{\infty} f^2 dx \geq \int_{x_0-t}^{x_0+t} f^2 dx \geq \int_{x_0-t}^{x_0+t} (f_0 - \delta - |x - x_0| f_1)^2 dx = \frac{2}{3} (f_0 - \delta)^3 / f_1 .\]

Letting \(\delta \to 0\), we obtain the assertion of the lemma.
6. Proofs of Theorems 3.2 and 3.3

The following is the basic lemma we shall need for Theorem 3.2.

**Lemma 6.1:** Under the hypotheses of Theorem 3.2, there exist constants $z_1, z_2, q_0$ and $\mu$ (the last two positive) such that

\[
U(x - ct - z_1) + U(-x - ct - z_1) - 1 - q_0 e^{-\mu t} \leq u(x, t) \\
\leq U(x - ct - z_2) + U(-x - ct - z_2) - 1 + q_0 e^{-\mu t}.
\]

**Proof:** First, note that (3.3) implies $c < 0$. The right-hand inequality of (6.1) follows from the proof of Lemma 4.1. More precisely, that proof shows that $u(x, t) \leq U(x - ct - z_2) + q_1 e^{-\mu_0 t}$ for some $z_2, q_1$ and $\mu_0$. The same argument applied to $u(-x, t)$ reveals as well that $u(x, t) \leq U(-x - ct - z_2') + q_1' e^{-\mu_0 t}$. Since decreasing $z_2$ and $z_2'$ and increasing $q_1$ and $q_1'$ strengthens the inequality, we may assume $z_2 = z_2' < 0$, $q_1 = q_1'$. Hence

\[
u \text{ct} + z_2\]

\[
U(x - ct - z_2) \leq U(-x - ct - z_2') + q_1 e^{-\mu_0 t}.
\]

If $x > 0$, then the monotonicity of $U$ and its exponential rate of convergence to its limits at $\pm \infty$ imply

\[
1 - U(x - ct - z_2) \leq 1 - U(-ct - z_2) \leq Ke^{\nu |ct+z_2|}
\]

for some positive constants $\nu$ and $K$. Furthermore

\[
U(x - ct - z_2) \geq U(-x - ct - z_2)
\]

for $x > 0$, and so from (6.2),

\[
u \text{ct} + z_2\]

\[
U(x - ct - z_2) + U(x - ct - z_2) - 1 + q_0 e^{-\mu_0 t} + Ke^{\nu |ct+z_2|}
\]

\[
u \text{ct} + z_2\]

\[
U(x - ct - z_2) + U(x - ct - z_2) - 1 + q_0 e^{-\mu_0 t},
\]

-36-
if we choose \( \rho_0 > \rho_1 \) and further require \( \rho_0 \) to be small enough and 
\((-z_2)\) large enough. A similar argument may be used for the range \( x < 0 \).

We shall now prove the left-hand inequality of (6.1). Let 
\[
\psi(x,t) = U(x,t) + U(x,t) - 1 - \rho(t),
\]
where \( \xi_+ = x - ct - \xi(t) \), \( \xi_- = -x - ct - \xi(t) \), \( U_\pm(x,t) = U(\xi_\pm) \), for some \( \rho(t) > 0 \) and \( \xi(t) < 0 \) (with \( \xi'(t) > 0 \)) to be determined. Then 
\[
\begin{align*}
\text{Nu} = u_t - u_{xx} - f(u) \\
= -\xi'(t)(U'(\xi_+) + U'(\xi_-)) - (U'(\xi_+) + U'(\xi_-)) - c(U'(\xi_+) + U'(\xi_-)) - q'(t)
- f(U_+ + U_- - 1 - \rho).
\end{align*}
\]
Since \( U'' + cU' + f(U) = 0 \), we have 
\[
(6.3) \quad \text{Nu} = -\xi'(t)(U'(\xi_+) + U'(\xi_-)) + f(U_+) + f(U_-) - f(U_+ + U_- - 1 - \rho) - q'(t).
\]
Let \( \rho_0 \) and \( \rho_2 \) be such that 
\[
\alpha_1 < 1 - \rho_2 < 1 - \rho_0 < \alpha_1 + \eta,
\]
and let \( \delta \) be as in the proof of Lemma 4.1. As in that proof, we then see that for some \( \rho_1 > 0, \)
\[
f(U_-) - f(U_- - (1 - U_+ + \rho)) \leq -\rho_1(l - U_+ + \rho)
\]
for \( 1 - \delta < U_- < 1, 0 < l - U_+ + \rho \leq \rho_2 \). This latter inequality will be guaranteed if \( 0 \leq \rho \leq \rho_0, x > 0 \), and \( (-\xi) \) is sufficiently large, for then 
\[
1 - U_+ + \rho \leq 1 - U(-\xi) + \rho_0' \leq \rho_0' + Ke^{-\nu|\xi|} \leq \rho_2.
\]

We finally note that \( U'(\xi_+) > 0 \) and \( f(U_+) \leq b(l - U_+) \) for some \( b > 0 \).
Therefore we have from (6.3) that for \( 1 - \delta \leq U_- \leq 1, \ 0 \leq q \leq q_0' \),
x \geq 0, \((-\xi)\) sufficiently large, and \( \xi' > 0 \),
\[
Nu \leq -\mu_1(l - U_+ + q) + b(l - U_+) - q' = (b - \mu_1)(l - U_+) - \mu_1 q - q'
\]
\[
\leq bKe^{-\nu|\xi + ct|} - \mu_1 q - q'.
\]
Setting \( q = q_0' e^{-\mu_2 t} \) for \( 0 < \mu_2 < \mu_1 \), we have for the above range,
\[
Nu \leq bKe^{-\nu|\xi + ct|} - (\mu_1 - \mu_2)q_0' e^{-\mu_2 t} \leq 0,
\]
provided \( \mu_2 < \nu c \) and \((-\xi)\) is sufficiently large.

A similar argument holds for \( 0 \leq U_- \leq \delta, \ 0 \leq q \leq q_0', \ x \geq 0 \), provided
that \( u \geq 0 \). Finally for \( \delta \leq U_- \leq 1 - \delta, \ x \geq 0 \), we have
\[
U_+ + U_- \geq \beta > 0,
\]
\[
f(U_-) - f(U_+ + U_- - 1 - q) \leq C(1 - U_+ + q),
\]
\[
f(U_+) \leq b(l - U_+) \leq bKe^{-\nu|\xi + ct|},
\]
so that from (6.3),
\[
Nu \leq -\beta \xi'(t) + (C + b)Ke^{-\nu|\xi + ct|} + (C + \mu_2)q_0' e^{-\mu_2 t}.
\]
We now choose \( \xi(t) \) so that
\[
-\beta \xi'(t) + (C + b)Ke^{-\nu|\xi + ct|} + (C + \mu_2)q_0' e^{-\mu_2 t} = 0,
\]
with \( \xi(0) = \xi_0 \) sufficiently large and negative. Then from the above we
obtain \( Nu \leq 0 \) for all \((x, t)\) with \( x \geq 0 \), \( u(x, t) > 0 \). A similar argument
shows that \( Nu \leq 0 \) for \( x \leq 0 \) as well.
Now \( \text{Max}[0, u(x, t)] \) will be a subsolution if we can show that
\[
\varphi(x) \geq u(x, 0). \quad \text{But}
\]
\[
u(x, 0) = U(x - \xi_0) + U(-x - \xi_0) - 1 - q_0' < 1 - q_0' < \alpha_1 + \eta \leq \varphi(x)
\]
for \( |x| \leq L \), and
\[
u(x, 0) \leq 0 \leq \varphi(x)
\]
for \( |x| \geq M \), for some \( M \) depending on \( \xi_0 \). Therefore if \( L \geq M \), we shall have \( u(x, 0) \leq \varphi(x) \) for all \( x \).

With this condition on \( L \), it now follows that
\[
u(x, t) \geq u(x, t) \geq U(x - ct - \xi(\infty)) + U(-x - ct - \xi(\infty)) - 1 - q_0' e^{-\mu_2 t}
\]
We set \( z_1 = \xi(\infty) \) and \( \mu = \text{Min}[\mu_2, \mu_0] \), and this completes the proof.

Lemma 6.2: Let \( f \) and \( \varphi \) satisfy the hypotheses of Theorem 3.2. There exist functions \( \omega(\varepsilon) \) and \( T(\varepsilon) \), defined for small positive \( \varepsilon \) and satisfying \( \lim_{\varepsilon \to 0} \omega(\varepsilon) = 0 \), such that if
\[
|u(x, t_0) - U(x - ct_0 - x_0)| < \varepsilon
\]
for some \( x_0, t_0 > T(\varepsilon) \), and all \( x < 0 \), then
\[
|u(x, t) - U(x - ct - x_0)| < \omega(\varepsilon)
\]
for all \( t > t_0, x < 0 \).

Proof: Consider the subsolution \( \nu(z, t) \) used in the proof of Lemma 4.1.
We express it in the original coordinates as
\[
u(x, t) = \nu(x - ct, t) = U(x - ct - \xi(t)) - q_0 e^{-\mu t},
\]
where \( \xi = \xi_1 + \xi_2 e^{-\mu t} \). It was shown that if \( \mu \) is sufficiently small (positive) and \( \xi_2 = A \frac{q_0}{\mu} \) for a certain constant \( A \mu \) depending only on \( \mu \) (see (4.4)), then for arbitrary \( \xi_1 \) and \( q_0 \),

\[
Nu = u_t - u_{xx} - f(u) < 0.
\]

We shall now use \( u \) (with appropriate \( \xi_1, q_0 \) and \( \mu \)) as a comparison function in the region \( x < 0, t > t_0 \). If we can show that \( u \leq u \) on the boundary \( \{x = 0\} \cup \{t = t_0\} \), then it will follow that \( u(x, t) \leq u(x, t) \) in the quarter-plane under consideration.

First, consider the portion \( \{t = t_0\} \) of the boundary. From (6.4) we have

\[
u(x, t_0) \geq U(x - ct_0 - x_0) - \varepsilon.
\]

If we now set \( q_0 = \varepsilon e^{\mu t_0}, \xi_2 = \varepsilon A \mu e^{\mu t_0}, \) and \( \xi_1 = x_0 - \varepsilon A \mu \), then

\[
u(x, t_0) = U(x - ct_0 - x_0) - \varepsilon \leq u(x, t_0).
\]

Next, consider the portion \( \{x = 0\} \). From (6.1) and the exponential approach of \( U(z) \) to its limits, we have, for some \( v, M_1 \),

\[
u(0, t) \geq 2U(-ct - z_1) - 1 - q_0' e^{-\mu t} = 1 - q_0' e^{-\mu t} - 2(1 - U(-ct - z_1))
\]

\[
\geq 1 - q_0' e^{-\mu t} - M_1 e^{-v|c|t},
\]

the primes added to distinguish these constants from the \( q_0 \) and \( \mu \) in (6.5). On the other hand, for \( t \geq t_0 \),

\[
u(0, t) = U(-ct - \xi(t)) - q_0 e^{-\mu t} < 1 - q_0 e^{-\mu t} = 1 - \varepsilon e^{-\mu(t-t_0)}.
\]
Thus

\( (6.6) \quad u(0, t) - u(0, t) \geq \varepsilon e^{-\mu(t-t_0)} - M_1 e^{-\nu |c| t} - q_0' e^{-\mu t} \).

The constant \( \mu \) can be taken as small as desired. We choose it so that \( 0 < \mu < \mu', \mu < \nu |c| \). Then from (6.6),

\[
\begin{align*}
\frac{-\mu(t-t_0)}{\mu t_0} - (M_1 + q_0') e^{-\mu t} & \geq (\varepsilon - (M_1 + q_0') e^{-\mu t_0}) e > 0
\end{align*}
\]

for sufficiently large \( t_0 \) (depending on \( \varepsilon \)).

This completes the comparison argument, and we conclude that for \( t \geq t_0, x < 0 \),

\[
\begin{align*}
u(x, t) & \geq u(x, t) = U(x - ct - \xi(t)) - \varepsilon e^{-\mu(t-t_0)} \\
& \geq U(x - ct - x_0) - \omega(\varepsilon).
\end{align*}
\]

A similar type of argument can be used to show that \( u(x, t) \leq U(x - ct - x_0) + \omega(\varepsilon) \), and this completes the proof of the lemma.

**Proof of Theorem 3.2:** We define the "left truncation"

\[
u_{\ell}(x, t) = \begin{cases} 
  u(x, t), & x < 0, \\
  1 - \xi(x)(1 - u(x, t)), & x \geq 0,
\end{cases}
\]

where \( \xi(x) \in C^\infty(-\infty, \infty), \xi(x) \equiv 1 \text{ for } x \leq 0, \xi(x) \equiv 0 \text{ for } x \geq 1, \) and \( \nu_{\ell}(z, t) = u_{\ell}(x, t) = u_{\ell}(z + ct, t) \).

Then with the aid of Lemma 6.1 and essentially the same proof as in Lemma 4.3, we conclude that \( \nu_{\ell} \) satisfies (4.5), and hence (as in Lemma 4.4) the set \( \{\nu_{\ell}(\cdot, t), t \geq \delta\} \) is relatively compact in \( C^2(-\infty, \infty) \).
Exactly as in Lemma 4.5, we next establish that

$$\lim_{t \to \infty} \left| v_{1}(z, t) - U(z - x_0) \right| = 0$$

for some $x_0$, uniformly in $z$.

It is now trivial to extend the proof in §5 to show that

$$\left| v_{1}(z, t) - U(z - x_0) \right| \leq Ke^{-\omega t},$$

which establishes (3.5a).

The symmetrical argument establishes (3.5b), completing the proof of Theorem 3.2.

The following lemmas lead to the proof of Theorem 3.3.

Lemma 6.3: Under the hypotheses of Theorem 3.3, the following holds for some numbers $a_1, a_2, q_0$ and $\mu$ (the last two positive):

$$u_1(x - c_1t - a_1) - q_0e^{-\mu t} \leq u(x, t) \leq U_2(x - c_2t - a_2) + q_0e^{-\mu t}. \quad (6.7)$$

Proof: Taking sufficiently the left-hand inequality, we observe that it follows at once from the left-hand inequality of Lemma 4.1 applied to the $u$-interval $(u_1, u_2)$.

For simplicity, we assume from now on that $c_1 < 0 < c_2$. If this is not the case, we may use a moving coordinate frame to reduce the problem to one for which it is so.

As in the proof of Theorem 3.2 above, we define the left truncation

$$u_{1}(x, t) = \begin{cases} 
    u(x, t), & x < 0, \\
    u_2 - \xi(x)(u_2 - u(x, t)), & x \geq 0
\end{cases}$$

and $v_{1}(z, t) = u_{1}(x, t) = u_{1}(z + c_1t, t)$, where $z = x - c_1t$. 

-42-
Lemma 6.4: For some numbers \( a_1, a_3, t_0, q_0 \) and \( \mu \) (the last three positive),

\[
U_1(z - a_1) - q_0 e^{-\mu t} \leq u(z, t) \leq U_1(z - a_3) + q_0 e^{-\mu t}
\]

for \( t \geq t_0 \).

Proof: The left inequality follows directly from Lemma 6.3, and so we prove only the right one. Let \( \eta \) be such that \( \limsup_{x \to -\infty} \varphi(x) < \eta < a_1 \). For some constants \( X_0, \gamma, \) and \( k \), to be determined below, let

\[
V(x) = \begin{cases} 
\eta, & x \leq X_0 \\
\eta + \gamma(x - X_0)^2, & x \geq X_0 
\end{cases}
\]

and \( u(x, t) = \min\{u_3, V(x + kt)\} \). First, it is clear that \( V \geq \varphi \) for large enough negative \( X_0 \). We so choose \( X_0 \).

For \( V = \eta \), we have \( u = \eta \) and \( Nu = -f(\eta) > 0 \), since \( a_1 \) is the first zero of \( f \) greater than \( u_1 \).

For \( \eta < V < u_3 \), we have

\[
Nu = kV - V'' - f(V) = 2k \gamma \xi - 2\gamma - f(V),
\]

where \( \xi = x + kt - X_0 \). But

\[
f(V) \leq f(\eta) + m(V - \eta) \quad (\text{for} \; V \geq \eta, \; \text{some} \; m > 0) = f(\eta) + m \gamma \xi^2,
\]

so that

\[
Nu \geq -f(\eta) - 2\gamma + 2k \gamma \xi - m \gamma \xi^2.
\]

We first choose \( \gamma \) so small that \(-f(\eta) - 2\gamma > 0\), then \( k \) so large that \( 2k \gamma \xi - m \gamma \xi^2 \geq 0 \) for \( \xi \) such that \( V \) is in the indicated range.
This shows that \( \bar{u} \) is a supersolution, and so \( u \leq \bar{u} \). In particular, it follows that at each value of \( t > 0 \),

\[
(6.9) \quad u(x, t) \leq \eta < \alpha_1, \text{ for } (-x) \text{ large enough.}
\]

Next we observe that since \( U_2(z) \leq u_2 + Ke^{-\omega_2 |z|} \) for \( z \leq 0 \), the right-hand inequality in (6.7) implies

\[
(6.10) \quad u(x, t) \leq u_2 + Ke^{-\omega_2 t}
\]

for \( x \leq 1 \).

We now consider the function

\[
\bar{u}(x, t) = U_1(x - c_1 t + \xi(t)) + q_0 e^{-\mu_2 t}
\]

in the domain \( x \leq 1 \), \( t \geq t_0 \). With appropriately chosen \( \xi \), \( q_0 \), \( \mu_2 \), and \( t_0 \), it will be a supersolution.

First of all, from the proof in Lemma 4.1, where a similar comparison function was used, we know that \( Nu \geq 0 \), provided \( q_0 \) and \( \mu_2 \) are sufficiently small, and \( \xi' = -\xi_1 e^{-\mu_2 t} \) for some appropriate \( \xi_1 \).

We shall show that \( \bar{u}(x, t) \geq u(x, t) \) for \( t = t_0 \) and/or \( x = 1 \).

First, with \( t_0 \) to be specified later, we choose \( q_0 \) so that \( q_0 e^{-\mu_2 t_0} = \eta \).

Taking the constants \( K \) and \( \omega_2 \) from (6.10), we note that

\[
(6.11) \quad u_2 + Ke^{-\omega_2 t} \leq U_1(1 - c_1 t) + \eta e^{\mu_2 (t_0 - t)}
\]

for sufficiently large \( t_0 \), \( t \geq t_0 \), and sufficiently small \( \mu_2 \), by virtue of the facts that \( c_1 < 0 \) and \( U_1(z) \rightarrow u_2 \) exponentially as \( z \rightarrow \infty \). We
choose $t_0$ and $\mu_2$ so that (6.11) holds for $t \geq t_0$, and also so that

the last term in (6.10) satisfies

$$\omega_2 t_0 < \eta.$$  

(6.12)

Next, we choose $X$ so large that (from (6.9)) $u(x, t_0) \leq \eta$ for $x \leq -X$, and $\xi(t_0)$ so large that

$$u_1(x - c_1 t_0 + \xi(t_0)) + q_0 e^{-\mu_2 t_0} = U_1(x - c_1 t_0 + \xi(t_0)) + \eta \geq u_2 + K e^{-\omega_2 t_0},$$

for $x \geq -X$. This is possible, by virtue of (6.12) and the fact that $U_1(\infty) = u_2$.

For $t = t_0$, (6.10) and (6.13) yield that $u(x, t_0) \leq \bar{u}(x, t_0)$. For $x = 1$, (6.10), (6.11), and the fact that $\xi(t) > 0$ imply $u(1, t) \leq \bar{u}(1, t)$ for $t \geq t_0$. By the maximum principle, we conclude that

$u(x, t) \leq \bar{u}(x, t) \leq U_1(x - c_1 t - a_3) + q_0 e^{-\mu_2 t}$ for all $x \leq 1, t \geq 0$. Since $u(x, t) = v_1(x - c_1 t, t)$ for $x \leq 0$, this establishes the right side of (6.8) for $z \leq -c_1 t = |c_1| t$. But for small $\mu$ and large $t$,

$$U_1(z - a_3) + q_0 e^{-\mu t} > u_2 \geq v_1(z, t) \text{ for } z > |c_1| t,$$

and so (6.8) can be guaranteed by (if necessary) further reducing $\mu$ and increasing $t_0$. This completes the proof of the lemma.

Proof of Theorem 3.3: With inequality (6.8) at hand, we may prove, as in the proof of Theorem 3.1, that for some $x_1$,

$$\lim_{t \to \infty} |v_1(z, t) - U_1(z - x_1)| = 0,$$

uniformly in $z$. And again using the argument in §5, we find that
\[ |v_1(z, t) - U_1(z - x_1)| \leq Ke^{-\omega t}, \]

and hence

(6.14) \[ |u(x, t) - U_1(x - c_1t - x_1)| \leq Ke^{-\omega t} \]

for \( x \leq 0 \). A similar argument using the right truncation yields

(6.15) \[ |u(x, t) - U_2(x - c_2t - x_2)| \leq Ke^{-\omega t} \]

for \( x \geq 0 \). Combining (6.14) and (6.15), we obtain (3.7), completing the proof.

THE APPROACH OF SOLUTIONS OF NONLINEAR DIFFUSION EQUATIONS TO TRAVELLING FRONT SOLUTIONS

The paper is concerned with the asymptotic behavior as \( t \to \infty \) of solutions

\[ u(x,t) \quad \text{of} \quad u_t - u_{xx} - f(u) = 0 \quad (x \in (-\infty, \infty)) \]

in the case \( f(0) = f(l) = 0 \), \( f'(0) < 0 \), \( f'(l) < 0 \). Commonly, a travelling front solution \( u = U(x - ct) \), \( U(-\infty) = 0 \), \( U(\infty) = 1 \), exists. The following types of global stability results for fronts and various combinations of them are given:
1. Let \( u(x,0) = u_0(x) \) satisfy \( 0 \leq u_0 \leq 1 \). Let
\[
a_- = \limsup_{x \to -\infty} u_0(x),
\]
\[
a_+ = \liminf_{x \to \infty} u_0(x).
\]
Then \( u \) approaches a translate of \( U \) uniformly in \( x \) and exponentially in time, if \( a_- \) is not too far from 0, and \( a_+ \) not too far from 1.

2. Suppose \( \int_0^1 f(u)du > 0 \). If \( a_- \) and \( a_+ \) are not too far from 0, but \( u_0 \) exceeds a certain threshold level for a sufficiently large \( x \)-interval, then \( u \) approaches a pair of diverging travelling fronts.

3. Under certain circumstances, \( u \) approaches a "stacked" combination of wave fronts, with differing ranges.
