MECHANICS OF COMPOSITE MATERIALS†

by

G. A. Hegemier¹

ABSTRACT

This report summarizes the results of a theoretical study of wave propagation, diffusion, and damage accumulation in composite materials.

¹ Sponsored by the United States Air Force Office of Scientific Research, at the University of California, San Diego. F49620-76-C-0024

¹ Professor, Department of Applied Mechanics and Engineering Sciences, University of California, San Diego, La Jolla, California.
1. RESEARCH OBJECTIVES

Research under the subject Contract represents a continuing effort to construct viable nonlinear micro-mechanical continuum models to predict the thermomechanical response of advanced composite materials. The thermomechanical processes under study include:

- Linear and nonlinear wave propagation
- Linear and nonlinear diffusion (thermal and hygrothermal)
- Mechanisms and accumulation of damage.

The thermomechanical measures include:

- Global stress, deformation, temperature, internal energy fields
- Local stress, deformation, temperature, internal energy fields
- Residual properties of damaged composites.

2. RESEARCH PROGRESS

2.1 Discussion

Excellent progress has been made to date in modeling both laminated and fibrous composites as homogeneous continua with microstructure. The resulting theory is generally referred to as a "Theory of Interacting Continua" or a "Mixture Theory with Microstructure". In contrast to classical theories

---

Previous work was conducted under AF-AFOSR Grant 70-1975 and AF-AFOSR Contract 75-2870.
with similar titles, the governing equations are completely specified by a
knowledge of the initial microstructural geometry of the composite, the
component constitutive relations, and the component interface physics.
In further contrast to classical theories, the current model provides infor-
mation on stress, displacement, strain, temperature, and internal energy
fields within the microcomponents as well as global measures of these
quantities. The present theory also accounts for debonding at the micro-
component interfaces - a basic damage mode. Models incorporating crack
distributions throughout the constituents are under study.

The most general mathematical model considered to date is a non-
linear, anisotropic, thermomechanical mixture theory with microstructure.
Particular, simplified forms of this model have been developed to cover
special cases of composite geometry, material constitutive relations, and
physical processes or problems. In all cases, however, theoretical
construction is based upon one of two basic methods which are in turn
based upon an asymptotic scheme in which dominant signal wavelengths
associated with the physical process are assumed to be large in comparison
with typical composite microdimensions. An explanation of the foregoing
construction methods, as well as a number of interesting examples, can
be found in Appendix II.

The composites studied using the above asymptotic technique range
from elementary laminated to complex three-dimensional advanced
composites. In addition to certain model composites, materials have included quartz phenolic, carbon phenolic, carbon carbon, and graphite epoxy. Representative problem areas include nose tips, heat shields, engine blades, nozzles, and hygrothermal environments.

Cases completed and in publication thus far include:

- A general theory for wave propagation in linear elastic and linear-viscoelastic laminated composites with isotropic laminae;
- A general theory for linear thermal diffusion in laminated composites with isotropic laminae;
- A "first order" theory for linear wave propagation in anisotropic laminates with oblique layup;
- "First order" theories for wave propagation, diffusion, and debonding in unidirectional fibrous composites with cylindrical fibers of arbitrary cross section;
- "First order" nonlinear, anisotropic and isotropic, thermo-dynamic theories for wave propagation, diffusion, and damage accumulation due to debonding in both laminated and fibrous composites of specific types.

In the general linear cases above, a hierarchy of models is systematically defined by the order of the truncation of the asymptotic sequence involved in the theoretical construction process. Retention of all terms in this sequence leads to a formally exact theory. Retention of only the zeroth-order plus first order terms results in a so-called "first order"
theory which can be cast in the form of a mixture theory. The latter usually constitutes an adequate micromechanical model of a composite for engineering purposes. All nonlinear models are "first order" theories.

The first order models for laminates and fibrous composites incorporate the effects of arbitrary fiber geometry, anisotropy, and interface debonding. In addition to diffusion, a thermodynamic theory of elastic-plastic wave propagation under finite deformation has been developed. The constitutives laws of the microcomponents currently in publication relate the mean stress (trace of the stress tensor) to density and internal energy by a Mie-Grüneisen caloric equation of state and the stress deviator tensor to the rate-of-deformation tensor by an elastic-perfectly plastic relation of the von Mises type; extension to general anisotropic plasticity utilizing a plastic potential and an associated flow rule is under development. Constituent debonding and component-interface physics is governed by a Coulomb frictional-type relation; the latter constitutes the present measure of "damage"; extension of this measure to include microcracking throughout the components is, as was noted previously, under study.

In the case of linear elastic wave propagation, model accuracy has been demonstrated by comparison of phase velocity spectra with exact and/or experimental data. Accuracy superior to existing theories has been observed, as well as first order model applicability down to wave-lengths on the order of typical composite microdimensions (when the energy
is partitioned primarily in the first mode). In addition, a number of transient pulse cases have been treated; these exhibit good correlation with exact and/or experimental data. A sampling of typical transient pulse results for both laminated and unidirectional fibrous composites is illustrated in Figs. 1-4 of Appendix 1. Typical transient wave propagation results for a complex, advanced, three-dimensional composite are given in Figs. 8-10 of Appendix 1. Complete details, including extensive phase-velocity-spectra-calculations, can be found in the appropriate references listed under Section 2.3.

In the case of large deformations and elastic-plastic wave propagation, theoretical transient pulse-results for propagation parallel to the fibers of a unidirectional fibrous composite have been compared with data from a 2D-Lagrangian finite difference-code (CRAM); the latter is essentially exact. As can be observed from Appendix I, Figs. 11-14, the agreement between "exact" and approximate calculations was found to be excellent.

Model accuracy in the case of interface debonding has, to-date, been assessed by comparison with experimental data on delaminated plates composed of alternating layers of Polymethyl Methacrylate (PMMA, Rohm and Haas Type A), and 6061-T6 aluminum. The laminae of the composite were oriented perpendicular to the impact plane, and struck by a projectile fired from a 10 cm bore light gas gun. On the basis of averaged particle velocity measured at the rear face of the specimen, the model hypothesized yields excellent correlation with the experimental
results. The test setup and typical results are illustrated in Figs. 15-18 of Appendix I.

In addition to the above, studies concerning the accuracy of the thermal-portion of the continuum models were undertaken. In particular, diffusion-type processes in a laminated composite with periodic microstructure were examined. Solutions for the lowest-order models were compared with "exact" results from a finite difference code. For most cases the lowest-order "effective conductivity" theory was found to yield good results. For exceptional problems requiring a higher-order theory, a modified version of the lowest-order theory was found to yield excellent correlation between exact and approximate solutions. For many problems of the diffusion-type, these elementary equations may offer an attractive alternative to other means for obtaining solutions. Typical results for the case of heat propagating normal to the layers of the laminated composite of Fig. 1, Appendix I, are illustrated in Figs. 19 and 20 of Appendix I. In each case a uniform temperature $T_0$ is applied to $y = 0$ from $t = 0$ and $t = t_0$ while the boundary temperature is zero for all other time. (Here $\Delta = h_1 + h_2$, $c$, $\rho$ = heat capacity of $\alpha$-material, $k_\alpha$ = thermal diffusivity). It is emphasized here that, although Figs. 19, 20 refer to a one-dimensional example, the theory is valid for three-dimensional problems. The one-dimensional case was selected mainly because the most severe test of the theory occurs when heat flow is
normal to the laminates (since material properties are discontinuous in this direction).

In the last interim scientific report, it was noted that a major development in theoretical modeling was effected during the previous research period. The development allows treatment of arbitrary fiber geometry and arrays. Basically, the task of constructing mixture theories has been partitioned into two isolated steps. The first step involves the determination of the general mixture equations for a particular problem class; these equations involve coefficients which must be determined from the detailed microstructural geometry, interface data, and constitutive relations. The second step defines the constants via a quasi-static "microboundary value problem" (MVP).

Resolution of the MVP is carried out by a variational-based finite element method. The procedure has been applied to diffusion and wave propagation in unidirectional composites. Here important information has been obtained regarding the accuracy of the concentric cylinders approximation used frequently in practice for circular fibers in a hexagonal array and for rectangular fibers in a similar array. Extension of the procedure to arbitrary three dimensional geometries is under development.

A discussion of the above subject matter can be found in the survey paper listed under Section 2.3. For the readers convenience, the latter is included as Appendix II of this report.
Finally, during the current research period another major advance in our theoretical modeling procedure was accomplished. This development allows a unified treatment of laminated and fibrous composites, and provides a substantial increase in model accuracy. The mixture theory construction procedure in this case is based upon the Regular Asymptotic Method in conjunction with the use of a multi-variable expansion procedure. The approach has been successfully applied to both wave propagation and heat conduction in laminated composites. Fibrous composites are under study. The resulting form of the mixture theory indicates a significant flaw currently exists in some general phenomenological mixture theories. Reports and publications on this subject are in preparation.

2.2 Research Applications

The fundamental concepts embodied in the aforementioned wave propagation studies have been successfully employed in an applied research effort to model 1-D (FMI COMRAD) and AVCO 3DQP quartz phenolic composites. These models, and the resulting numerical code (TINC) are presently in practical use by the engineering profession. Typical results for 3DQP are illustrated in Figs. 5 - 10 of Appendix I.

APPENDIX I

Compendium of Typical Theoretical Results

Presented in this Appendix is a sampling of typical transient pulse and diffusion calculations carried out using the Theory of Interacting Continua (TINC). The cases discussed include laminated and unidirectional fibrous composites as well as a complex 3-dimensional layup. Results of the TINC theory for each example are compared to experimental data.

**Laminated Composites**

The geometry of the laminated composites studies is illustrated in Fig. 1. One problem of interest is that of symmetric (P) wave propagation parallel to the layers, with material behavior restricted to the linear elastic range. A comparison of TINC and experimental results is given in Fig. 2. The experimental results were reported by Whittier and Peck [1] for specimens composed of Thornel (high modulus carbon) fibers reinforcing a carbon phenolic matrix. Specimens of 1/4-inch thickness were subjected to a uniform pressure at the left boundary, with a step function time-dependence induced by a gas dynamic shock wave of about 70 psi. The numerical calculations were initiated by impacting a step function velocity of 7.786 cm/sec to both constituents at the boundary. While this condition does not correspond precisely to the experiment, it was felt that the error introduced would be negligible when far removed...
from the front surface. Figure 2 depicts the comparison between experiment and theoretical results for averaged rear surface velocity, normalized on the boundary input velocity. Since absolute times were not measured in the tests, theoretical and experimental results were matched at their respective first peak arrivals. In the figure, results from the full TINC equations solved numerically are denoted "Continuum mixture theory." The results denoted "Simplified theory" are for an elementary form of the TINC theory admitting a closed-form solution.

Unidirectional Fibrous Composite

The TINC theory has been applied to the problem of wave propagation parallel to the fibers of a unidirectionally reinforced composite with hexagonal array. The hexagonal array is approximated by concentric, linearly elastic cylinders as illustrated in Fig. 3.

In Fig. 4, transient pulse data predicted by TINC is compared with experimental data on a unidirectional quartz phenolic fibrous composite. The experiments were subjected to a 70 psi step function in pressure via a shock tube. The figure depicts the comparison between the experimental and TINC theory code predictions of area-averaged rear surface velocity. Results of the simplified TINC theory are also portrayed. Once again the experimental and theoretical results are matched at their first peak arrivals since absolute arrival times were not measured experimentally. As was the case in Fig. 2, the times shown are those
predicted by the theory.

Three-dimensional Layups

Predictions of transient pulse behavior from the TINC theory have been compared to experimental results for a 3-dimensional quartz phenolic composite (3DQP) manufactured by AVCO. A representative selection of the results are given here.

A "block" 3DQP specimen (Fig. 5) was subjected to shock tube tests by the Aerospace Corporation. The test procedure is the same as that used for laminated and fibrous composites and is described above. Once again the theoretical and experimental boundary conditions are not identical, but this discrepancy is expected to introduce little error. The averaged rear surface velocity measured by experiment is compared to that predicted by the TINC theory in Fig. 6. Also shown are results predicted by the elementary "Head of the Pulse" approximate [2].

The experimental data has been forced to coincide with the theoretical at \( \frac{V}{V_o} = 1/3 \) since absolute arrival times were not measured.

Another set of relatively low pressure wave propagation experiments were performed at the Air Force Weapons Laboratory using a light gas gun and "mid-space" 3DQP specimens, shown in Fig. 7. In this test, three specimens of different thicknesses were mounted on a single target and impacted with a .01-inch mylar flyer. The input stress profiles for the three specimens are illustrated in Fig. 8. For the TINC calculations,
input velocity time-histories corresponding to the stress-time data of Fig. 8 were used. A comparison of experimental and theoretical results for the thickest of these specimens is shown in Fig. 9. Since absolute arrival times were not measured, the two curves are forced to coincide at their peak pressures. The agreement here is excellent, especially in view of the fact that the wave is measured only 2-1/2 microdimensions from the front surface. Also, with the 10kb input stress, this is a non-linear calculation.

The AFWL also performed a series of high-pressure gas gun experiments on "mid-space" 3DQP specimens (Fig. 7). Experimental and theoretical data are compared in Fig. 10. The observed agreement indicates that the thermodynamic and nonlinear constitutive behavior incorporated into the TINC theoretical model are adequate. Note that here the rear surface velocity is measured only 1-1/2 microdimensions from the front surface. Thus, as before, the TINC theory, though derived as an "outer" solution, yields surprisingly good results even at locations quite near the boundary.

Comparison of TINC and 2-D Finite Difference Code

It is of interest to compare the results from a TINC calculation to those of a typical two-dimensional Lagrangian finite difference code which is essentially exact. Such a code (CRAM) is available at Systems, Science and Software, Inc. The two codes were compared for the
concentric cylinder geometry of Fig. 11. Computer costs for CRAM were approximately 500 times those for running the TINC code. Several typical results are illustrated in Figs. 12-14 for a square wave input velocity (shown as problem #2 on Fig. 11). Once again, the calculations were carried out within a few microdimensions of the boundary.

**Debonding of Constituent Interfaces**

Model accuracy in the case of interface debonding or cracking has, to date, been assessed by comparison with experimental data dealing with delaminated plates composed of alternating layers of Polymethyl Methacrylate (PMMA, Rohm and Haas Type A), and 6061-T6 aluminum. The laminae of the composite were oriented perpendicular to the impact plane, and struck by a projectile fired from a 10 cm bore light gas gun. On the basis of averaged particle velocity measured at the rear face of the specimen, the model hypothesized yields excellent correlation with the experimental results.

The test setup employed is illustrated in Fig. 15. Typical correlation between theoretical and experimental results is shown in Figs. 16-18. Complete details can be found in reference [13].

**Diffusion**

The laminated geometry of Fig. 1 was selected to evaluate the continuum model construction procedure for diffusion problems (a
complete discussion of this work can be found in reference [4]). The
case of heat propagation normal (in the y-direction) to the layers was
selected for a comparison of exact and continuum theory solutions since
it is known that this case represents the most severe test of the latter.
Figure 19 represents a case of similar material properties whereas
Fig. 20 illustrates the comparison for widely differing material prop-
erties. Continuum theory-results were obtained via closed-form
solutions for a square-wave temperature input at the boundary y = 0.
"Exact" results were obtained using a finite difference code. The
calculations illustrate the ability of the first-order theory to model
microstructure details and closely match the exact data.

MIXTURE THEORIES WITH MICROSTRUCTURE FOR WAVE PROPROPAGATION AND DIFFUSION IN COMPOSITE MATERIALS

Two procedures for constructing mixture theories with microstructure are discussed for wave propagation and thermal diffusion processes in binary laminated and fibrous composites. Each method proceeds from the composite microstructure and is based upon an asymptotic scheme wherein the ratio of transverse-to-longitudinal characteristic times associated with a physical process is assumed to be small. The methods retain considerable information regarding the mechanical and/or diffusive fields within the microcomponents. Theoretical results are compared with both experimental and exact data in an effort to evaluate model accuracy. The presentation includes treatment of geometric, constitutive, and interface nonlinearities.

1. INTRODUCTION

A considerable number of continuum theories have been proposed for thermomechanical processes in composites. The continuum theory of mixtures represents one of the more important and successful theoretical descriptions of such multiphase materials. According to this concept, the composite constituents are modeled, at each instant of time, as superposed continua in space. Each continuum is allowed to undergo individual deformations. The microstructure of an actual composite is then simulated by specifying the interactions between the continua.

Mixture theories for multiphase materials have been developed from both macrostructural and microstructural viewpoints. The vast majority of activity, however, has been directed toward the former, which concerns the formulation of a general theoretical framework for classes of mixtures based upon certain phenomenological postulates that avoid detailed microstructural considerations. Excellent accounts of this approach can be found in [1-3].

The development of mixture theories from the microstructural viewpoint represents a more difficult task. The reward, however, is a model - which shall be called a mixture theory with microstructure - that is completely determined by the geometry and constitutive relations of the individual components and which provides, to a certain degree of accuracy, information concerning microstructure fields. Of course, the price one must pay for such detail is often a case-by-case study rather than a general theory. Nevertheless, it should be recognized that, while general macrostructural-based theories may appear more elegant, such theories may not be practical for many applications due to the unreasonable burden placed upon the experimentalist to determine a multitude of constants and/or functions.
In this presentation, focus is placed upon several recent works by the author and co-workers concerning the construction of mixture theories with microstructure for laminated and fibrous composites. The discussion is limited to thermomechanical processes in composites with initial periodic microstructure. Particular emphasis is placed upon wave propagation and thermal diffusion.

The presentation is divided into five sections. The methodology associated with two theoretical construction techniques is given in Section 2 along with a brief survey of applications. These techniques are demonstrated via two examples in Sections 3 and 4. Finally, in an effort to illustrate the applicability and utility of the techniques, two applications to nonlinear problems are discussed in some detail in Section 5; these include comparisons between mixture theory, exact and/or experimental results.

2. METHODOLOGY AND SURVEY

A variety of construction procedures may be used to generate mixture theories with microstructure. Two such procedures are selected for discussion herein in view of their observed success in describing thermomechanical processes in composite materials.

The first procedure, which is illustrated in Section 3 by an elementary example, is the Differential-difference Method. This approach has been used to develop continuum models of wave propagation in linear elastic [4-9, 26] and linear viscoelastic [9-10] laminated composites, wave propagation in linear elastic fibrous composites [7-11], wave propagation and debonding in laminated composites [12], and thermal diffusion in laminated composites [13, 14]. The method consists of eight basic construction steps which may be summarized as follows:

1) the field quantities (all dependent variables) of each composite constituent are expanded in a suitable spatial series (this expansion, which amounts to discretization of the component domains, may range from a Taylor series for sufficiently simple geometries to topological multiplexes [15], e.g., finite elements, for complex geometries);
2) recurrence relations for the expansion coefficient-functions are obtained by use of the field equations and the series is telescoped; 3) application of interface continuity conditions lead to differential (in time) - finite difference (in space) equations; 4) an associated set of differential (in time) - functional difference equations is observed to contain, as a solution subset, solutions of the finite difference relations; 5) solutions of the functional equations are smooth fields which take on exact values at discrete spatial points; these smooth fields are now employed as dependent variables; 6) all spatial differences are expanded in a Taylor series - an operation which furnishes partial differential equations, i.e., a continuum model; 7) nondimensional variables and a small parameter representing the ratio of typical micro-to-macro dimensions is introduced and the operators are truncated according to an asymptotic procedure; 8) mixture equations result by algebraic manipulation.

The second procedure, illustrated in Section 4 by an elementary example, is the Regular Asymptotic Method. This approach has been
used to model nonlinear wave propagation in laminated [16] and fibrous [17-19] composites, and thermal diffusion in fibrous composites [20-21]. The method consists of six basic construction steps which may be summarized as follows: 1) based upon the particular composite and the process considered, an estimate of the order of magnitude of all field variables is made; 2) the field equations are re-scaled such that all dependent variables are \( O(1) \); in the process a small parameter is introduced which constitutes a measure of the ratio of micro-to-macro-dimensions of the problem; 3) the conservation equations are averaged to obtain a standard mixture form; 4) the scaled field variables are expanded in a regular asymptotic series; 5) the two lowest order systems (including interface conditions) are used to obtain expressions for the interaction terms and the constitutive relations; 6) the constants involved in 5) are obtained from the solution of a static micro boundary value problem defined over a unit cell; a variational principle - based finite element method is suggested to resolve this boundary value problem.

A judicious choice of a particular method depends upon the problem. The Differential-difference Method is best suited to linear problems and elementary geometries such as laminates. Here formally exact relations may be obtained in many cases. The Regular Asymptotic Method is, on the other hand, applicable to nonlinear problems and complex geometries. In this case one is usually content with the first few terms of the asymptotic series.

3. EXAMPLE I: WAVE PROPAGATION

For the purpose of illustrating the Differential-difference Method, consider wave propagation in a periodic array of linearly elastic, homogeneous and isotropic laminae, perfectly bonded at all interfaces as illustrated in Fig. 1. Let \( y \equiv x_2 \) for notational convenience and assume a state of uniaxial motion in the \( y \)-direction; i.e., the case of one-dimensional longitudinal waves propagating normal to the laminae. Restricting attention to small isothermal deformations, the appropriate conservation and constitutive equations are

\[
(\partial_y \sigma - \rho \partial_t u)(\alpha,k) = 0 \quad , \quad (\sigma - (\lambda+2\mu)\partial_y u)(\alpha,k) = 0 ,
\]

while the interface continuity conditions are

\[
\{u,\sigma\}^{(1,k)}(h^{(1)},t) = \{u,\sigma\}^{(2,k)}(-h^{(2)},t) ,
\]

\[
\{u,\sigma\}^{(1,k+1)}(-h^{(1)},t) = \{u,\sigma\}^{(2,k)}(h^{(2)},t) .
\]

In the above the superscripts \((\alpha,k)\) refer to the \(k\)th layer of the \(\alpha\)th constituent, \(\alpha = 1,2; k = 1,2,3\ldots\). The variable \(y(y,y)\) is a local coordinate with origin at the midplane of the \((\alpha,k)\) layer; \(\sigma \equiv \sigma_{22}\) and \(u \equiv u_2\) are normal stress and displacement (subscripts on \(\sigma\) and \(u\) have been dropped for brevity). The quantities \(\rho(\alpha), h(\alpha), \lambda(\alpha), \mu(\alpha)\) are mass density, layer half thickness and Lamé constants for the \(\alpha\) - constituent. In addition \(\partial_y(\cdot) \equiv \partial(\cdot)/\partial y, \partial_t(\cdot) \equiv \partial(\cdot)/\partial t\).

Wave motion in the composite is completely specified by (1), (2)
together with initial conditions at \( t=0 \) and boundary data on \( y=0 \), \( H(H \leq \infty) \).
The objective of the subsequent work is to replace this set of equations (infinite if \( H = \infty \)) by a single set of partial differential equations which represent a continuum mixture theory.

3.1 Expansion, Recurrence Relations

Let us expand the stress and displacement about each lamina mid-plane as follows:

\[
g(y^{(\alpha,k)}, t) = \sum_{n=0}^{\infty} g^{(n)}(t) y^{(\alpha,k)} / n!.
\]

Here \( g \) represents any of \( \sigma^{(\alpha,k)} \), \( u^{(\alpha,k)} \). Upon substituting (3) into (1) and equating powers of \( y^{(\alpha,k)} \), one obtains the differential-recurrence relations

\[
c^{(\alpha)} \{u,\sigma\}^{(\alpha,k)}(y^{(\alpha,k)}, t) = \frac{2}{\alpha} \{u,\sigma\}^{(\alpha,k)}(\alpha^{(\alpha,k)}, (\alpha^{(\alpha,k)}) = \frac{\sigma^{(\alpha,k)}}{E^{(\alpha,k)}}^{(\alpha,k)}(n+1).
\]

Here

\[
c^{(\alpha)} = \frac{\sigma^{(\alpha)}}{E^{(\alpha)}} = \frac{\rho^{(\alpha,k)}}{E^{(\alpha,k)}} = (\lambda+2\mu)^{(\alpha,k)},
\]

where \( n = 0, 1, 2, \ldots; k = 1, 2, 3, \ldots; \alpha = 1, 2 \). With use of the recurrence relations (4a), the series (3) may be telescoped as follows

\[
\{u,\sigma\}^{(\alpha,k)}(y^{(\alpha,k)}, t) = C^{(\alpha,k)} \{u,\sigma\}^{(\alpha,k)}(0) + \frac{\sigma^{(\alpha,k)}}{E^{(\alpha,k)}}^{(\alpha,k)}(k),
\]

where \( C^{(\alpha,k)} \), \( S^{(\alpha,k)} \) are formal differential operators defined by

\[
C^{(\alpha,k)} = \cosh(c^{(\alpha)} y^{(\alpha,k)}),
\]

\[
S^{(\alpha,k)} = \sigma^{(\alpha,k)} - 1 \sinh(c^{(\alpha)} y^{(\alpha,k)}).
\]

The functions \( \sigma^{(0)}(\alpha,k)(t), u^{(0)}(\alpha,k)(t) \) represent stress and displacement at the midplane of the \( (\alpha,k) \) layer; these serve as dependent variables in the ensuing analysis.

3.2 Transition to a Continuum Theory

Substitution of the expansions (5) into the interface conditions (2) furnishes the following differential (in time) - finite difference (in space) equations with dependent variables defined at discrete points along the \( y \)-axis:

\[
C^{(\alpha,k+1)}(u^{(\alpha,k)}_{(0)} + \sigma^{(\alpha,k+1)}_{(0)}) - 2C^{(\beta,k)}(\beta_{(0)} - h^{(\alpha)} \sigma^{(\alpha,k+1)}_{(0)} - \sigma^{(\alpha,k)}_{(0)} = 0,
\]

\[
C^{(\alpha)}(\sigma^{(\alpha,k)}_{(0)} + \sigma^{(\alpha,k)}_{(0)}) - 2C^{(\beta,k)}(\beta_{(0)} - \rho n h^{(\alpha)} \sigma^{(\alpha,k+1)}_{(0)} - \sigma^{(\alpha,k)}_{(0)} = 0.
\]
\[ \alpha, \beta = 1, 2; \alpha \neq \beta. \]

If one now defines the fields
\[
[u, \sigma]^{(\alpha)}(y,t) = \{u, \sigma\}^{(\alpha,k)}(y,t) \quad \text{for} \quad y \in (Y^{(\alpha,k)} - h^{(\alpha)}, Y^{(\alpha,k)} + h^{(\alpha)}),
\]
\[
= \{0, 0\} \quad \text{for} \quad y \in (Y^{(\beta,k)} - h^{(\beta)}, Y^{(\beta,k)} + h^{(\beta)}),
\]
\[ \alpha, \beta = 1, 2; \alpha \neq \beta; \] and if one notes that
\[
[u, \sigma]^{(\alpha,k)}(t) = \{u, \sigma\}^{(\alpha,k)}(Y^{(\alpha,k)}, t) \quad , \quad Y^{(2,k)} = Y^{(1,k)}, \Delta = h^{(1)} + h^{(2)},
\]
then (7) can be rewritten in the form
\[
C^{(\alpha)}[u^{(\alpha)}(y+\Delta,t) + u^{(\alpha)}(y-\Delta,t)] - 2C^{(\beta)}(\beta)(y,t)
\]
\[
- h^{(\alpha)}E^{(\alpha)} - S^{(\alpha)}(\alpha)(y+\Delta,t) - S^{(\alpha)}(\alpha)(y-\Delta,t)] = 0 , \quad (10a)
\]
\[
C^{(\alpha)}[\sigma^{(\alpha)}(y+\Delta,t) + \sigma^{(\alpha)}(y-\Delta,t)] - 2C^{(\beta)}(\beta)(y,t)
\]
\[
- h^{(\alpha)}S^{(\alpha)}(\alpha)(y+\Delta,t) - S^{(\alpha)}(\alpha)(y-\Delta,t)] = 0 , \quad (10b)
\]
\[ \alpha, \beta = 1, 2; \alpha \neq \beta. \] Equations (10a, b) were obtained by replacing the fields \( \sigma^{(\beta)}(Y^{(\beta,k)}, t) \) and \( \sigma^{(\beta)}(Y^{(\beta,k)}, t) + \Delta t, \) etc., by the smooth fields \( \sigma^{(\beta)}(y,t), \)
\[
u^{(\alpha)}(y+\Delta, t), \) etc., defined over the entire domain of the composite; here \( Y^{(\alpha,k)} \) denotes the midplane of the \((a,k)\) layer (see Fig. 1).

The functional difference equations (10a, b) contain, as a subset, the solutions of the finite difference equations (7). That is, the new fields satisfy (7) at \( y = Y^{(\alpha,k)} \). Therefore, the new dependent variables \( u^{(\alpha)}, \sigma^{(\alpha)} \) are functions defined for all \( y \) which assume exact values at layer midplanes. Assuming the admissibility of such expansions, all sums and differences are now expanded about \( \Delta = 0 \) in a Taylor series; this leads to the partial differential equations
\[
C^{(\alpha)}C^{(\alpha)}u^{(\alpha)} - h^{(\alpha)}E^{(\alpha)} - S^{(\alpha)}(\alpha)Y^{(\alpha,k)} - C^{(\beta)}(\beta)(y,t) = 0 ,
\]
\[
C^{(\alpha)}C^{(\alpha)}\sigma^{(\alpha)} - h^{(\alpha)}E^{(\alpha)} - S^{(\alpha)}(\alpha)Y^{(\alpha,k)} - C^{(\beta)}(\beta)(y,t) = 0 , \quad (11)
\]
\[ \alpha, \beta = 1, 2; \alpha \neq \beta, \] where \( \bar{C}, \bar{S} \) are formal differential operators of the form
\[
\bar{C} = \cosh(\Delta \alpha), \quad \bar{S} = (\Delta \alpha)^{-1} \sinh(\Delta \alpha). \quad (12)
\]
Equations (11) constitute a continuum model of the composite. The dependent variables \( u^{(\alpha)}, \sigma^{(\alpha)} \) of (11) can be used to reconstruct the microstructural fields through (5)(noting (8)).

### 3.3 Scaling

Let the typical "macrodimension" of the problem be \( \ell \) and the typical "microdimension" be \( \Delta \). The quantity \( \ell \) represent a dominant signal wavelength associated with wave motion. Introduce the non-
dimensional quantities

\[ \xi = y/t, \quad \tau = tc/t, \quad \epsilon = \Delta/t, \quad \Sigma^{(\alpha)} = \sigma^{(\alpha)}/(\rho c)^2, \quad \eta^{(\alpha)} = u^{(\alpha)}/(\alpha) \]

(13)

where \( p, c \) denote appropriate mixture density and wave speed. Then (11) becomes

\[ \begin{align*}
&\mathcal{C}^{(\alpha)} \frac{\partial \eta^{(\alpha)}}{\partial \xi} - \mathcal{E}^{(\alpha)} \Sigma^{(\alpha)} - \mathcal{E}^{(\beta)} \Sigma^{(\beta)} = 0, \\
&\mathcal{C}^{(\alpha)} \frac{\partial}{\partial \tau} \left( \gamma^{(\alpha)} \right)^2 - \mathcal{E}^{(\alpha)} \Sigma^{(\alpha)} - \mathcal{E}^{(\beta)} \Sigma^{(\beta)} = 0,
\end{align*} \]

(14)

where

\[ \begin{align*}
&\mathcal{C}^{(\alpha)} = \cosh(\epsilon \gamma^{(\alpha)} \partial \tau), \quad \mathcal{E}^{(\alpha)} = (\epsilon \gamma^{(\alpha)} \partial \tau)^{-1} \sinh(\epsilon \gamma^{(\alpha)} \partial \tau), \\
&\mathcal{C}^{(\alpha)} = \cosh(\epsilon \partial \xi), \quad \mathcal{E}^{(\alpha)} = (\epsilon \partial \xi)^{-1} \sinh(\epsilon \partial \xi), \\
&\gamma^{(\alpha)} = (c/c^{(\alpha)})^{\alpha/n}, \quad n^{(\alpha)} = h^{(\alpha)}/(\Delta), \quad \eta^{(\alpha)} = \eta^{(\alpha)} / \rho, \quad \delta^{(\alpha)} = \rho c^{(\alpha)}/E^{(\alpha)}.
\end{align*} \]

(15)

The governing equations (14) are now scaled such that, if \( y \in (0, t) \) and \( \tau \in (0, t/c) \), then \( \xi \in (0, 1) \) and \( \tau \in (0, 1) \); that is, the macrodimension is now \( O(1) \) while the microdimension is \( O(\epsilon) \). Thus, it is evident that all foregoing Taylor expansions about \( \Delta = 0 \) are in fact expansions about \( \epsilon = 0 \); further, all operators are power series in \( \epsilon^{2n}, \quad n = 0, 1, 2 \ldots \). Such expansions are not required to converge, but only be asymptotic as \( \epsilon \to 0 \).

3.4 Binary Mixture Theories

With some algebraic manipulations, equations (14) may be rewritten in a form characteristic of binary-type mixture theories as follows:

\[ \begin{align*}
&\mathcal{C}^{(\alpha)} \frac{\partial \eta^{(\alpha)}}{\partial \xi} - \mathcal{E}^{(\alpha)} \Sigma^{(\alpha)} - \mathcal{E}^{(\beta)} \Sigma^{(\beta)} = (-1)^{\alpha+1} \mathcal{R}, \\
&\mathcal{C}^{(\alpha)} \frac{\partial}{\partial \tau} \left( \gamma^{(\alpha)} \right)^2 - \mathcal{E}^{(\alpha)} \Sigma^{(\alpha)} - \mathcal{E}^{(\beta)} \Sigma^{(\beta)} = (-1)^{\alpha+1} \mathcal{R},
\end{align*} \]

(16)

\( \alpha = 1, 2 \). Here

\[ \begin{align*}
&\mathcal{C}^{(2)} \Sigma^{(2)} - \mathcal{C}^{(1)} \Sigma^{(1)} = \mathcal{C}^{(2)} \eta^{(2)} - \mathcal{C}^{(1)} \eta^{(1)}, \\
&\mathcal{C}^{(2)} = 1/2! + (\epsilon \partial \xi)^2/4! + (\epsilon \partial \xi)^4/6! \ldots.
\end{align*} \]

(16)

The bracket in (16a) suggests a momentum equation while that of (16b) has the character of a constitutive relation. The quantities \( \mathcal{P} \) and \( \mathcal{R} \) represent constituent interaction terms.

A mixture theory of order \( n \) is now defined as those equations obtained from (16a, b) by truncating the operators \( \mathcal{C}^{(\alpha)} \mathcal{C}^{(\alpha)} \) and \( \mathcal{E}^{(\alpha)} \mathcal{E}^{(\alpha)} \), as well as the \( \mathcal{C}^{(\alpha)} \) in \( \mathcal{P} \) and \( \mathcal{R} \), after \( O(\epsilon^{2n-2}) \) terms. In particular, a mixture theory of order 1 is, under this definition, given by
Equations (17a) may be interpreted as mixture momentum relations and (17b) as mixture constitutive equations. The interaction terms in this formulation are proportional to displacement and stress differences, respectively.

The operator $\partial_\xi$ preceding the left side of each equation (17a, b) can be eliminated by expanding the dependent variables in regular asymptotic series in $\epsilon$. The result, upon retaining $O(\epsilon^2)$ terms only, is

$$\partial_\xi \Sigma^{(\rho p)} - \rho^{(\rho p)} \partial_\tau \eta^{(\sigma)} = (-1) \alpha^+ \rho^+ , \quad \partial_\xi (\Sigma^{(\eta \Sigma - c\Sigma)}(\alpha)) = (-1) \alpha^+ \Sigma^+ (17a, b)$$

$\varepsilon \rho^+ = \Sigma^{(2)} - \Sigma^{(1)} , \quad \varepsilon \eta^+ = \eta^{(2)} - \eta^{(1)} . \quad (18c, d)$

These equations may be interpreted as mixture momentum relations and (17b) as mixture constitutive equations. The interaction terms in this formulation are proportional to displacement and stress differences, respectively.

The operator $\partial_\xi$ preceding the left side of each equation (17a, b) can be eliminated by expanding the dependent variables in regular asymptotic series in $\epsilon$. The result, upon retaining $O(\epsilon^2)$ terms only, is

$$\partial_\xi \Sigma^{(\rho p)} - \rho^{(\rho p)} \partial_\tau \eta^{(\sigma)} = (-1) \alpha^+ \rho^+ , \quad \partial_\xi (\Sigma^{(\eta \Sigma - c\Sigma)}(\alpha)) = (-1) \alpha^+ \Sigma^+ (17a, b)$$

where $\alpha$ is a constant which is a complicated function of composite geometry and material properties. The quantities $\Sigma^{(\rho p)}$, $\rho^{(\rho p)}$ here play the role of "partial" stresses and densities; their physical interpretation, however, is not obvious. Details concerning the derivation of (18), which shall be called a modified (first order) mixture theory, can be found in [4].

Let us now consider the limit as $\epsilon \to 0$ in (16). If it is assumed, that $\iota$ and $c$ may be selected such that $\partial_\tau (\_ ) = O(1), \rho^{(\rho )} = O(1), n = 1, 2, \ldots$, where ( ) represents $\eta^{(\alpha)}$ or $\Sigma^{(\alpha)}$, as $\epsilon \to 0$ (i.e., as the ratio of micro-to macro-dimensions vanishes), then (16) reduces in dimensional form to

$$[\partial_y (n (1) \rho (1) + n (2) \rho (2)) (n E (1))^{-1} + n (2) E (2))^{-1} \partial_t ] [u, \sigma^{(\alpha)}] = 0. \quad (19)$$

Therefore, the theory is nondispersive as $\epsilon \to 0$, a result to be expected. Equation (19) implies that the appropriate mixture density $\rho$, modulus $E$, and wave speed $c$, are

$$\rho = n (1) \rho (1) + n (2) \rho (2) , \quad E = n (1) E (1) + n (2) E (2) , \quad c^2 = E / \rho. \quad (20)$$

### 3.5 Phase Velocity Spectra

It is evident that the foregoing theory represents a long wavelength, low frequency approximation of composite wave motion. A natural question concerns the range of validity of this approximation. A convenient indication of the comparative accuracy of an approximate theory can be obtained by studying the phase velocity spectrum. Assuming steady-state sinusoidal wave trains, equations (16), (17) or (18) become a set of homogeneous algebraic equations from which the relation between wave number $k$ and phase velocity $c_p$ is calculated. A typical comparison of exact, first order, and modified (first order) mixture phase velocity spectra is shown in Fig. 2 for a Polymethyl methacrylate (PMMA) - 304 stainless steel composite. The data shown represents the first mode of propagation down to the cutoff frequency associated with the first "stop band". The exact spectrum results from retaining all terms in the operators of (16) and is identical to that given by
Rytov [22]. Comparisons such as Fig. 2 indicate that reasonable accuracy may be expected from a theory of order 1 down to wavelengths equal to several microdimensions for problems where the energy is partitioned primarily in the first mode. This is quite a remarkable result for such an elementary theory. Additional details concerning the phase velocity spectrum as well as transient pulse calculations and an associated discussion concerning initial and boundary conditions can be found in [4-9].

4. EXAMPLE 2: HEAT CONDUCTION

For the purpose of illustrating the Regular Asymptotic Method, consider a linear thermal diffusion process in a periodic, two-dimensional array of unidirectional fibers of arbitrary cross section embedded in a matrix, as illustrated in Fig. 3a. Let a "cell" be associated with each fiber as depicted in Fig. 3b. Each such cell consists of regions $A^{(1)}$ and $A^{(2)}$ occupied by the fiber and matrix, respectively, with unit outer normals $N_1^{(1)}$ and $N_1^{(2)}$. The interface between the two constituents shall be denoted by $I$, and the outer boundary of the cell by $C$. With respect to rectangular Cartesian coordinates $x_1, x_2, x_3$ as shown in Fig. 3a, let the composite occupy the domain $0 \leq x_3 \leq L$, $-\infty < x_2 < \infty$, $-\infty < x_1 < \infty$. Assume that the two constituents in each cell are homogeneous and isotropic with a perfect interface (no thermal resistance). Finally, let the initial conditions, and the boundary conditions on $x_3 = 0, L$ be such that the temperature field is similar in each cell. In view of the last premise it is sufficient to consider a typical cell with zero heat flux normal to the boundary $C$. Consequently the basic equations for the temperature fields $T^{(\alpha)}$ and heat flux vectors $Q_{i}^{(\alpha)}$, $\alpha = 1, 2$, are

\[
\begin{align*}
(Q_{j,j} + dT^{(\alpha)})^{(\alpha)} &= 0 \quad (Q_{i} + kT_{,i})^{(\alpha)} = 0 \quad \text{on } A^{(\alpha)}; \\
(Q_{\beta}^{(2)}N_{\beta}^{(2)}) &= 0 \quad \text{on } C; \quad T^{(1)} = T^{(2)} \quad \text{and} \quad (Q_{\beta}^{(1)} - Q_{\beta}^{(2)})N_{\beta}^{(1)} = 0 \quad \text{on } I.
\end{align*}
\]

Equation (21a) is the conservation of energy; the relation (21b) is the Fourier heat conduction law; equation (21c) is a symmetry condition; and (21d) represents the interface continuity of temperature and normal heat flux (note $N_{\beta}^{(2)} = 0$). The superscript $\alpha = 1, 2$ refers to the fiber and the matrix, respectively. The quantities $d, k$ denote heat capacity and thermal conductivity, respectively. The notations $(\cdot )_{,i} = \partial (\cdot )/\partial x_{i}$ and $(\cdot )' = \partial (\cdot )/\partial t$ have been introduced for convenience.

4.1 Scaling

Equations (21), together with initial conditions at $t = 0$ and appropriate boundary data on $x_3 = 0, L$ specify a well posed problem involving three spatial variables $x_1$ and time, $t$. The objective of the subsequent analysis is to derive a continuum mixture theory governing the macroscopic diffusion process which involves only one spatial dimension ($x_3$)

*Latin and Greek subscripts imply Cartesian tensors and the usual summation convention with ranges from 1 to 3 and 1 to 2 respectively.
and yet reflects, at least approximately, the effect of conduction on the microscale. To this end, let $\Lambda$ and $\Delta$ be associated with typical "macroscopic" and "microscopic" observational dimensions, respectively. These lengths may be defined in terms of characteristic thermal diffusion times in the longitudinal and transverse directions according to

$$t(\Lambda) = \frac{d(m)^2}{k(m)} , \quad t(\Delta) = \frac{d(m)^2}{k(m)}$$  \hspace{1cm} (22)

where $d(m)$, $k(m)$ denote mixture heat capacity and thermal conductivity (to be defined later). In addition, it will be convenient to introduce a mixture heat flux $Q(m)$ based upon a reference temperature $T$, and a parameter $\epsilon$ as follows:

$$Q(m) = k(m) T/\Delta , \quad \epsilon = \Delta/\Lambda = \left(\frac{t(\Delta)}{t(\Lambda)}\right)^{\frac{1}{2}} \hspace{1cm} (23)$$

The quantity $\epsilon$ represents the ratio of micro-to-macro-dimensions of the composite.

With the aid of the foregoing definitions, the following nondimensional variables are introduced

$$\left(\xi_3, \xi_\beta\right) = \left(\frac{x_3}{x_\beta}\right)/\Delta , \quad \tau = t/t(\Lambda) , \quad \left(\xi_3, \xi_\beta\right) = \left(\frac{Q_3}{Q_\beta}\right) = \left(\frac{Q(m)}{Q(m)}\right) ,$$

$$\zeta(\alpha) = T(\alpha)/T , \quad \gamma(\alpha) = d(\alpha)/d(m) , \quad \lambda(\alpha) = k(\alpha)/k(m) ,$$  \hspace{1cm} (23a, b)

whence (21) become

$$\left(\sigma_{3,3} + \sigma_{3,\beta}\right)(\alpha) = 0 , \quad \left(\sigma_{3,3} - 2 \sigma_{3,\beta}\right)(\alpha) + \lambda(\alpha) \left(\zeta(3)_{3} \zeta(3)_{\beta}\right)(\alpha) = 0 \text{ on } C(\alpha) , \hspace{1cm} (24a, b)$$

$$\zeta(2)_{3} = 0 \text{ on } \tau ; \quad \zeta(1) = \zeta(2) , \quad \zeta(1)_{\beta} = 0 \text{ on } J . \hspace{1cm} (24c, d)$$

In (24) $\beta = 1, 2$ and $C(\alpha), J, C$ denote $A(\alpha), I, C$ in nondimensional form; the vectors $\nu(\alpha)$ are unit outer normals to the boundaries of $\left(\alpha\right)$; partial derivatives are now defined by $(\tau) , \quad i = \partial(1)/\partial \xi_1 , \quad (\tau') = \partial(1)/\partial \tau . \hspace{1cm} 4.2 \text{ Mixture Equations}$

Binary mixture equations for this problem can be immediately obtained by averaging (24a) over $C(\alpha)$ according to

$$\zeta(3, \tau) = \zeta(3) = \int \zeta(3, \tau) d\xi_1 d\xi_2 \hspace{1cm} (25)$$

where $\zeta(3)$ represents $\zeta(3)$ or $\zeta(3)$. This yields, after a little algebraic manipulation

$$\zeta(3)_{3} + \zeta(3, \beta) = (-1)^{\rho+1} \rho , \quad \rho = G^{-1} \int_{\beta} \nu_{\beta}^{(1)} d\zeta_{\beta} , \quad \nu_{\beta}^{(1)} = G^{-1} \int_{\beta} \nu_{\beta}^{(1)} d\zeta_{\beta} , \hspace{1cm} (26a, b)$$
where
\[ \mathcal{D}_3^{(ap)} = n^{(a)}(\mathcal{D}_3^{(a)})^{(a)}, \quad \mathcal{D}_3^{(ap)} = n^{(a)}(\mathcal{D}_3^{(a)})^{(a)}, \quad n^{(a)} = \mathcal{G}^{(a)}/(1 + \mathcal{G}^{(2)}). \] (27)

The quantities \( \mathcal{D}_3^{(ap)}, \mathcal{D}_3^{(ap)}, n^{(a)} \) represent partial heat fluxes, partial heat capacities, and volume fractions, respectively. The variable \( \rho \) is an interaction term reflecting heat transfer from the fiber to the matrix. At this stage the mixture equations (26) are exact. Approximations arise when one attempts to model the Fourier expressions for heat conduction, and the interaction term.

### 4.3 Asymptotic Expansions

A fundamental premise is now introduced: the ratio of the characteristic thermal diffusion times in the transverse and longitudinal (fiber axis) directions in small compared to unity, i.e.,
\[ \epsilon^2 = \frac{t_\Delta}{t_\Lambda} = \frac{(\Delta / \Lambda)^2}{2} \ll 1. \] (28)

Equation (28) is appropriate for many composites used for thermal protection. The premise (28) suggests the following regular asymptotic expansion for all dependent variables, denoted by \( G^{(a)}(\xi, \tau; \epsilon) \):
\[ G^{(a)}(\xi_1, \tau; \epsilon) = \sum_{n=0}^{\infty} \epsilon^n G_n^{(a)}(\xi_1, \tau). \] (29)

If (29) is substituted into the governing equations (24a, b) and the coefficients of similar \( \epsilon \)-order are equated, one obtains a system of equations for each \( n = 0, 1, 2, \ldots \). In what follows, a mixture theory is developed based on the lowest order system.

### 4.4 Interaction Term

The lowest order system corresponding to (24a, b) is
\[ (\mathcal{D}_j + \mathcal{D}_j^{(a)})^{(a)} = 0, \quad (\mathcal{D}_3 + \mathcal{D}_3^{(a)})^{(a)} = 0, \quad (\mathcal{G}_1 = \mathcal{G}_2 = 0)^{(a)}. \] (30a, b, c)

Equations (30c) yield
\[ \mathcal{G}_3^{(a)}(\xi, \tau) = \mathcal{G}_3^{(0)}(\xi, \tau), \] (31)

whence, to lowest order accuracy, equations (25), (27) furnish
\[ \mathcal{D}_3^{(ap)} = -\mathcal{G}_3^{(ap)}(\xi_3, \tau). \] (32)

In order to complete the mixture formulation, the functional dependence of the interaction term \( \rho \) on the averaged temperatures \( \rho^{(a)} \) must be determined. For this purpose it is necessary to consider \( \mathcal{D}_3^{(a)} \), \( \mathcal{D}_3^{(2)} \) and to satisfy the continuity of temperature including \( O(\epsilon^2) \) terms. To begin this task, one finds from (32) and (24b) that
\[ \mathcal{D}_3^{(a)} - \mathcal{D}_3^{(ap)}(\xi, \tau) \] (33)

Next, with use of (33) and (30b, c), equation (30a) becomes
\[ (\mathcal{K}(\alpha), \mathcal{J}(\alpha))_{\beta \beta} = \varphi(\xi_3, \tau) \]  

(34)

The functions \( \varphi(\alpha) \) can be related to \( n \), defined by (26b), by integration of (34) over \( C^{(\alpha)} \), use of Gauss' Theorem, and the symmetry condition (24c); the result is:

\[ n^{(\alpha)}(\alpha) = (-1)^{\alpha} \rho . \]  

(35)

Thus, one obtains the following relations for \( \varphi^{(\alpha)}(\alpha) \):

\[ n^{(\alpha)}(\alpha) \mathcal{J}^{(\alpha)}(\alpha), \beta \beta = (-1)^{\alpha} \rho \text{ on } C^{(\alpha)}(\alpha, \beta = 1, 2) . \]  

(36)

The appropriate boundary conditions are, from (24c, d),

\[ \mathcal{J}^{(2)}(2), \beta \beta = 0 \text{ on } C , \quad (\mathcal{K}^{(2)}(1) - \mathcal{K}^{(2)}(2), \beta \beta) \nu_{\beta} = 0 , \]  

\[ \mathcal{J}^{(2)}(2) - \mathcal{J}^{(2)}(1) = (\mathcal{J}^{(2)}(0) - \mathcal{J}^{(2)}(0))/\epsilon^2 \text{ on } \mathcal{J} . \]  

(37)

Equations (36), (37) constitute a "micro" boundary value problem in the \( \xi_1, \xi_2 \) - plane; the solution is unique within a function \( \mathcal{K}(\xi_3, \tau) \). Once \( \mathcal{J}^{(2)}(\alpha) \) are known, one can write

\[ \mathcal{J}^{(\alpha)}(\alpha) = [\mathcal{J}^{(\alpha)}(0) + \epsilon^2 \mathcal{K}^{(\alpha)}(\xi_3, \tau) + \epsilon \mathcal{J}^{(\alpha)}(\xi_1, \xi_2, \tau) + \mathcal{O}(\epsilon^4)] \]  

(38)

where

\[ \mathcal{J}^{(\alpha)}(\alpha) = \mathcal{J}^{(1)}(\alpha) , \quad \mathcal{J}^{(2)}(\alpha) = \mathcal{J}^{(2)}(2) - \mathcal{J}^{(2)}(0) - \mathcal{J}^{(1)}(2)/\epsilon^2 . \]  

(39)

Upon averaging (39), one obtains

\[ \mathcal{J}^{(\alpha)}(\xi_3, \tau) = \mathcal{J}^{(1)}(\xi_3, \tau) + \epsilon \mathcal{J}^{(\alpha)}(\alpha) . \]  

(40)

Hence, the interaction term can be written

\[ \rho = a(\mathcal{J}^{(1)a} - \mathcal{J}^{(2)a})/\epsilon^2 , \quad a = (\mathcal{J}^{(1)a} - \mathcal{J}^{(2)a})^{-1} . \]  

(41a, b)

Equations (41a), (32), (26a) close the mixture theory. The primary result is expression (41b), which can be used to determine the interaction coefficient, \( a \), for arbitrary fiber and/or cell geometry via the solution of a time independent problem defined over the unit cell. In terms of \( \mathcal{G}^{(\alpha)} \), this problem takes the form:

\[ n^{(\alpha)}(\alpha) \mathcal{G}^{(\alpha)}(\alpha), \beta \beta = (-1)^{\alpha} \rho \text{ on } C^{(\alpha)} ; \]  

(42)

\[ \mathcal{J}^{(2)}(2), \beta \beta = 0 \text{ on } C ; \quad \mathcal{J}^{(1)} = \mathcal{J}^{(2)} , \quad (\mathcal{K}^{(1)} - \mathcal{K}^{(2)}), \beta \beta \nu_{\beta} = 0 \text{ on } \mathcal{J} . \]  

(43)

\[ \mathcal{J}^{(1)} = 0 \text{ at point } 0(\xi_3(1)) . \]  

(44)

In general it is difficult to obtain an analytical solution to the above micro boundary value problem. As an alternative, a finite element procedure has been proposed [21] which may be utilized for
arbitrary two-dimensional cell geometry. This procedure is based upon a modified Reissner-type variational principle, the corresponding functional of which is defined by

\[ \Pi = \sum_{\alpha=1}^{2} \int_{\Gamma} \left( \mathcal{G}^{(\alpha)}(\gamma, \beta, \gamma^{(*)}(\alpha)) + \frac{(-1)^{(\alpha)}}{\mathcal{G}(\alpha)} \right) \mathcal{J} \, dG + \frac{\delta \mathcal{J}(\gamma^{(*)}(1) - \gamma^{(*)}(2))}{\mathcal{G}(\alpha)} \, ds \]  

which is defined in terms of \( \mathcal{G}^{(*)}(\alpha) \) on \( \mathcal{G}(\alpha) \) and \( \mathcal{J}^{(*)} \) on \( \mathcal{J} \). The equations for \( \gamma^{(*)}(\alpha) \) follow from the requirement \( \Pi \) be stationary with respect to arbitrary variations of \( \gamma^{(*)}(\alpha) \) and \( \gamma^{(*)} \); here \( \mathcal{J}^{(*)} \) is a Lagrange multiplier which physically represents the heat flux normal to the boundary \( \mathcal{J} \).

### 4.5 Numerical Results

The finite element procedure has been used for the solution of the temperature microstructure problem and the interaction coefficient for a variety of geometries and combination of material properties. Details of such calculations can be found in [21]. Here several results of particular interest are noted; properties used are listed in Table 3.

A frequent fibrous composite geometry is a hexagonal array of circular cylindrical fibers. In practice it is common to approximate the cell geometry of this case by concentric circular cylinders [20]. Numerical results, based on the theory presented herein, related to the accuracy of this approximation are shown in Fig. 4, where the interaction coefficient has been calculated as a function of fiber volume fraction and thermal conductivity. From the data, the conclusion can be drawn that for a practical range of fiber volume fractions, the concentric cylinder approximation can be used without any significant loss of accuracy.

For calculation of the interaction coefficient, the concentric circular cylinders approximation based on equal fiber volume fraction can also be used for composites containing square fibers arranged in a square array. This is borne out by the results shown in Fig. 5.

The fields \( \mathcal{J}^{(*)}(\xi_1, \xi_2) \) needed to calculate the interaction term can also be used for the calculation of the temperature distribution in a unit cell. From (38)-(40) one has

\[ \mathcal{J}^{(*)}(\xi_1, \gamma) = \mathcal{J}(\alpha) + a[\mathcal{J}(1a) - \mathcal{J}(2a)][\mathcal{J}^{(*)}(\alpha) - \mathcal{J}^{(*)}(\alpha)] \]  

In the right side of (46) the only quantity dependent upon inplane coordinates \( \xi_1 \) and \( \xi_2 \) is \( \mathcal{J}(\alpha) \). It follows, therefore, that curves of equal \( \mathcal{J}^{(*)}(\alpha) \) are also isothermal lines within the framework of the mixture theory. For this reason, and to illustrate the type of temperature microstructure that can be obtained from the mixture theory, contours of equal \( \mathcal{J}^{(*)}(\alpha) \), suitably normalized, are given in Fig. 6 for square fibers in a similar array.

Finally, an indication of the accuracy of the proposed mixture model and the construction procedure can be obtained by comparison of mixture-predicted response with 2D or 3D computer code calculations. This has been accomplished in [20] for the case of concentric circular
cylinders where two spatial dimensions and time are involved. Calculations were conducted to determine the evolution of the temperature field in a quiescent half-space $x_3 \geq 0$ subject to the boundary condition

$$T(0, r, t) = \begin{cases} 1, & 0 \leq t \leq t_0 \\ 0, & t > t_0 \end{cases}$$  \hspace{1cm} (47)$$

Both the mixture equations and the full 2D problem were solved by finite difference schemes [20]; the latter was used as the correlating norm for estimating the accuracy of the mixture theory solutions. Fig. 7 illustrates typical average temperature profiles in the two constituents after a short time following the termination of the temperature pulse. The ability of the mixture theory to predict the temperature microstructure is illustrated in Fig. 8; the radial distribution of temperature obtained from the mixture theory is almost identical to the exact solution.

4.6 Remarks

The significant feature of the above mixture theory, and of similar theories proposed for wave propagation [16-19], is that it converts what is essentially a three-dimensional problem to a problem involving a single spatial variable, without losing the essential details of local field distributions. The reduction in the number of dependent variables leads, of course, to a substantial increase in numerical efficiency.

5. SELECTED APPLICATIONS

Two applications involving nonlinear wave propagation are briefly reviewed in this section in an effort to demonstrate the utility of mixture theories with microstructure. The first involves delamination of laminated composites. The second concerns finite amplitude elastic-plastic wave propagation in fibrous composites.

5.1 Wave Propagation and Debonding in Laminated Composites

A "first order" mixture theory with microstructure has been developed in [12] for longitudinal wave propagation and debonding in a laminated, binary composite with periodic microstructure. The case considered concerns small isothermal deformations, linear elastic constituents, and a Mohr-Coulomb interface failure and slip model. In view of the last item the problem is nonlinear. With respect to Fig. 1, a condition of plane strain was assumed in the $x_3$-direction and wave motion yielding symmetric velocity $v_1$ and anti-symmetric velocity $v_2$ distributions with respect to the $x_2$-coordinate within each lamina. Theoretical construction was based on the Differential-difference Method. In dimensional form, and with reference to Fig. 1, the relevant equations are
\[
(\sigma_{11}) = \left(\begin{array}{cc}
p_{1} & \rho_{1} \\
p_{2} & \rho_{2}
\end{array}\right)
\]  

Equations (48a) are mixture momentum equations while (48b) represent mixture constitutive relations. The quantity \( P \) denotes a momentum interaction term. The variables \( \sigma_{11} \), \( \rho_{1} \) denote partial quantities and are defined by \( \rho_{1} = \rho_{1} + \rho_{2} \) where \( \rho_{1} = \rho_{1} + \rho_{2} \) is an averaged variable and \( n = h_{1} + h_{2} \). The quantity \( |P_{cr}| \) is related to the interface shear stress \( \sigma_{12}^{*} \) and normal stress \( \sigma_{22}^{*} \) by

\[
|h_{1} + h_{2}| |P_{cr}| = |\sigma_{12}^{*}| = A-B\sigma_{22}^{*} (\sigma_{22} \leq 0),
\]

\[
\sigma_{22}^{*} = (n_{1} + n_{2})(\sigma_{22}) = A-B\sigma_{22}^{*} (\sigma_{22} \leq 0),
\]

\[
|h_{1} + h_{2}| P_{cr} = |\sigma_{12}^{*}| = A-B\sigma_{22}^{*} (\sigma_{22} \leq 0).
\]

The constants \( A, B \) represent interface cohesion and frictional coefficients, respectively. The constants \( c(\alpha \beta) \), \( K \) are given in terms of the composite properties and geometry by

\[
K = \frac{3\mu_{1} \mu_{2}}{h_{1} + h_{2}}, \quad c(\alpha \beta) = n_{1} E_{1} + n_{2} E_{2}, \quad E_{1} = \frac{E(1)}{n_{1}} + \frac{E(2)}{n_{2}}, \quad E_{2} = \frac{E(1)}{n_{1}} + \frac{E(2)}{n_{2}},
\]

where \( \lambda, \mu \) are Lame' constants.

Considerable insight into the modeling capability of the above mixture theory can be gained by comparison of theoretical calculations with the experimental impact data on delaminated plates reported in [23]. The composites in this study consisted of alternating layers of Polymethyl methacrylate (PMMA, Rohm and Haas type A) 0.762 mm thick, and 6061-T6 aluminum 0.792 mm thick. The laminae of the composite were oriented perpendicular to the impact plane, and struck by a projectile from a 10cm bore light gas gun. An aluminum buffer plate 1.0cm thick was placed at the rear of the composite to improve planarity of the transmitted wave front. A transparent Dynasil 100 window followed the buffer, and a thin mirror was vapor deposited at the buffer/window interface. The motion of the mirror was monitored to within \( \pm 1.5 \times 10^{-5}\text{mm} \) by means of a displacement interferometer. The experimental configuration reproduced from [23] is depicted in Fig. 9. The shot matrix is summarized in Table 1.

The mixture theory, consisting of (48) was coded in finite difference form and solved numerically. Material properties for the
composite laminates, flyer plate material, buffer and window materials are listed in Table 1. Input to the computer code required only the material properties of all constituents, geometries of the test configuration, and flyer impact velocity. Numerical values for A and B were determined by a parametric study on the results of experimental shot number 2. They were found to be $A = 0.01 \times 10^9$ dyne/cm$^2$ and $B = 0.50$. All other correlations were performed using these values. Typical results are depicted in Figs. 10-12. As can be seen, agreement is generally excellent. Both theoretical and experimental results clearly exhibit the effects of bond breakage and delamination. This is manifested by the appearance of a precursor at the front of the wave profile and by greatly reduced oscillations behind the wave front when compared with both theoretical and experimental results for perfectly bonded wave-guides (e.g., see [12]).

5.2 Nonlinear Wave Propagation in Fibrous Composites

A binary, first-order mixture theory with microstructure has been developed in [17], using the Regular Asymptotic Method and the concentric cylinders approximation, for nonlinear waveguide-type propagation parallel to the fibers of a unidirectionally reinforced fibrous composite with initial periodic hexagonal array, Fig. 13. The resulting model incorporates the effects of thermodynamics, finite deformation, and elastic-plastic constituents. The constitutive relations for this analysis consist of a Mie-Grüneise- equation of state which relates mean pressure, density, and internal energy, and a von Mises-type yield criteria and associated (J2) flow rule which govern the stress derivatives. Under the assumption of an adiabatic process and isotropic, homogeneous constituents, the following mixture theory was obtained for composites with perfect bonds

(a) Continuity:

$$\sum_{\alpha=1}^{n} n^{(\alpha)} (\rho^{(\alpha)} v^{(\alpha)})_t = 0 , \quad (\rho^{(\alpha)})_{33} = -\left(\rho^{(\alpha)} v^{(\alpha)} \right)_3 + \rho^{(\alpha)} / \rho^{(\alpha)} .$$

(b) Momentum:

$$\left[ n^{(\alpha)} (-p+S^{(\alpha)})_{33} , \sum_{\alpha=1}^{n} n^{(\alpha)} (\rho^{(\alpha)} D^{(\alpha)} v^{(\alpha)})_t = \left( -1 \right)^{\alpha+1} p , \right.$$ \hspace{1cm} (51a)

where

$$2 \sum_{\alpha=1}^{n} B^{(\alpha)} (\alpha) \frac{P+(-1)^{\alpha} (-p+S^{(\alpha)})_{33}}{n^{(\alpha)}} ,$$

$$\left( (-1)^{\alpha} n^{(\alpha)} B^{(\alpha)} (\alpha) \right)_{33} = \frac{8(v^{(1a)} - v^{(2a)})}{r^2} ,$$

where

$$D^{(\alpha)} (\alpha) = m^{(\alpha)} D^{(\alpha)} (\alpha) + 2 \Lambda^{(\alpha)} (\alpha) , \quad D^{(\alpha)} (\alpha) = (\Lambda)^{\alpha} v^{(\alpha)} (\alpha)_3 .$$

(51b)
\[ B^{(1)} = 1, \quad B^{(2)} = -(2/n^{(2)})^2 \left( \frac{3}{2} - 2n^{(1)} + \frac{1}{2} n^{(1)} + \frac{1}{2} n^{(1)} \right) . \]  

(c) **Energy:**

\[
\sum_{\alpha=1}^{2} n^{(\alpha)} (p^{(\alpha)} + (p^{(\alpha)})_e) e^{(-p+S_{33}^{(\alpha)})(\alpha) v^{(\alpha)} v^{(\alpha)}} = (-p+S_{33}^{(\alpha)})(\alpha) v^{(\alpha)} v^{(\alpha)} = (-1)^{\alpha + 1} R, \]

\[ R = (-p+S_{rr}^{(1a)})(1a) . \]

(d) **Caloric equation of state (Mie-Grüneisen):**

\[ p^{(\alpha)} = g(p^{(\alpha)}) + \Gamma(p^{(\alpha)}) v^{(\alpha)} . \]

(e) **Stress derivative constitutive relations:**

\[
S_{33}^{(\alpha)} S^{(\alpha)} = \frac{4}{3} (v^{(\alpha)} - 1) f^{(\alpha)} , \quad S_{rr}^{(1a)} = \frac{1}{2} S^{(1a)} ,
\]

\[
S_{rr}^{(2a)} = - \frac{2}{3} (v^{(\alpha)} - 1)(1 + \frac{3}{2} \ln \frac{1}{n^{(2)}}) ,
\]

\[ S_{rr}^{(2a)} = - (S_{rr}^{(2a)} + S_{rr}^{(\alpha)}) . \]

where

\[ (p^{(\alpha)}) = 0 \quad \text{if} \quad \frac{1}{2} (p^{(\alpha)})^2 < \frac{1}{3} \gamma^{(\alpha)}, \quad \text{or} \quad D^{(\alpha)} J^{(\alpha)} < 0 ,
\]

\[ = \frac{3}{2} \gamma^{(\alpha)} \left[ S_{33}^{(\alpha)} v^{(\alpha)} v^{(\alpha)} + S_{33}^{(\alpha)} v^{(\alpha)} v^{(\alpha)} \right] \quad \text{if} \quad D^{(\alpha)} J^{(\alpha)} < 0.
\]

and

\[ J^{(\alpha)} = \frac{\gamma^{(\alpha)}}{3} . \]

(f) **Interface stress match:**

\[ (-p+S_{rr}^{(1a)})(x_3, t) = (-p+S_{rr}^{(2a)})(x_3, t) . \]

(g) **Volume fractions:**

\[ D_t^{(1a)} n^{(1)} = n^{(1)} f^{(1a)} + n^{(2)} n^{(2)} = 1 . \]

(b) **Definition of averages:**

\[ \langle x \rangle^{(1)} = \frac{1}{n_0^{(1)}} \int_0^{n_0^{(1)}} 2\pi r \langle x \rangle^{(1)} dr, \]
The dependent variables above number 14. These are \( n(\alpha) = n(\alpha, a) \), \( \rho(\alpha, a) \), \( v_{33}(\alpha, a) \), \( \rho_{33}(\alpha, a) \), \( S(\alpha, a) \), and \( e(\alpha, a) \) (\( \alpha = 1, 2 \)). The foregoing represent volume fraction, density, velocity component in the \( x_3 \)-direction, stress deviator component in the \( x_3 \)-direction, and internal energy, respectively.

Equations (51)-(56) constitute 14 independent relations for the above unknowns. The independent variables, which were originally \( r, \theta, x_3, t \) (see Fig. 13), are now \( x_3, t \) only. All equations are written in an Eulerian description. It should be noted that \( \alpha = 1 \) refers to the fiber while \( \alpha = 2 \) denotes the matrix.

In an effort to test the validity of the first-order mixture theory, a comparison was made between calculations performed using the quasi-one-dimensional mixture equations, and a formal two-dimensional solution of the concentric cylinders problem. The mixture solutions were obtained by writing (50-56) in finite difference form and solving simultaneously for the 14 dependent variables. The necessary numerical analysis and the resulting code is described in [24]. The two-dimensional solutions were generated using a well-known Lagrangian finite difference computer code called CRAM [25]. A typical cell of a quartz-phenolic composite occupying the half-space \( x_3 < 0 \) was selected for study. For computation in the range \( 0 \leq p \leq 30 \text{K bar} \) a Mie-Grüneisen relation of the form

\[
p(\alpha) = \sum_{i=1}^{3} \frac{H_i^{(\alpha)} \eta (\alpha)}{\rho(\alpha)} + \frac{C_f (\alpha)}{\rho(\alpha)} \eta, \quad \eta = \frac{n(\alpha)}{\rho(\alpha) - 1};
\]  

was used, where \( \rho(\alpha) \) denotes the initial density of material \( \alpha \), and \( H_i^{(\alpha)} \), \( C_f (\alpha) \) are material constants. The constituent material properties employed in all calculations are given in Table 2. Quiescent initial conditions were assumed. Boundary conditions consisted of a particle velocity of 0.5cm/\( \mu \) sec of 1.0-\( \mu \) sec duration applied uniformly to both constituents at \( x_3 = 0 \).

A comparison of mixture theory and two-dimensional finite difference code predictions of averaged constituent particle velocity as a function of time is illustrated in Figs. 14, 15. The two-dimensional code prediction, which resolves the particle velocity distributions in the radial direction, where averaged according to (57) in order to provide direct comparisons with the mixture theory. Results are shown for a propagation (\( x_3 \)-direction) distance of 0.5cm. Agreement between the finite difference and mixture theory calculations is judged to be excellent.

Finally, it is noted that on the same computer (aUNIVAC 1108), the CRAM calculation required roughly 500 times the computer time needed for the equivalent mixture calculation.
