0. Summary

Consider \( n \) blocks of \( k \) observations \((X_{ij}, \ldots, X_{kj})\),
j = 1, \ldots, n. Suppose \( X_{ij} \) are independent and 
\( P(X_{ij} \leq x) = F(x - \eta_j - \theta_i) \)
where \( \eta_j \) is the nuisance location parameter
of the \( j \)th block and \( \theta_i \) is the location parameter corre-
sponding to population \( \pi_i \) (1 \( \leq j \leq n, \ 1 \leq i \leq k \)).

We are interested in selecting populations associated with
large location parameter \( \theta \). To this end compute 
\( H_1 = \sum_{j=1}^{n} R_{ij} \)
where \( R_{ij} = [\# \text{ of } X_{i',j} \leq X_{ij} \ (1 \leq i' \leq k)] \), and
\( \overline{X}_i = n^{-1} \sum_{j=1}^{n} X_{ij} \)
and base the terminal statistical decision
on: \( \overline{X}_1, \ldots, \overline{X}_k \) (means procedure \( P_{MP} \) or \( H_1, \ldots, H_k \) (vector
rank procedure \( P_v \)). Fix \( t \) (1 \( \leq t < k \)) and consider the prob-
lem of selecting populations associated with the \( t \) largest
\( \theta \)'s based on: \( \overline{X}_1, \ldots, \overline{X}_k \) or \( H_1, \ldots, H_k \).

Key words and phrases. Robust selection procedures,
single-stage rule, block designs, asymptotic relative
efficiency, means procedure, indifference-zone approach,
counterexamples, least favorable configuration, large
sample approximation.
In this paper we investigate large sample behavior (as well as some fixed sample behavior) of \( P_V \). The asymptotic relative efficiency of \( P_V \) with respect to \( P_{MP} \) is also studied.

1. Introduction

Let \( X_{ij} \) \((j = 1, 2, \ldots, n_i; \ i = 1, 2, \ldots, k)\) be independent random samples drawn from populations \( \pi_1, \pi_2, \ldots, \pi_k \) with absolutely continuous distribution functions (df's) \( F(x - \theta_i) \).

Let \( \theta[1] \leq \ldots \leq \theta[k] \) denote the ordered values of the unknown \( \theta_i \), and let \( \pi(i) \) denote the population associated with \( \theta(i) \); these associations are assumed completely unknown. Often for some fixed \( t \) \((1 \leq t < k)\) an experimenter is interested in the problem of selecting the "so-called" \( t \) best populations, \( \pi(k-t+1), \ldots, \pi(k) \). For the selection of the \( t \) best populations, Bechhofer (1954) proposed the means procedure (denoted by \( P_{MP} \)) which selects, as being the \( t \) best populations, the \( t \) populations yielding the \( t \) highest sample means \( \bar{X}_i(= n_i^{-1} \sum_{j=1}^{n_i} X_{ij}) \): Bechhofer requires that the probability that the so-selected \( t \) populations are the \( t \) best [when this occurs, a Correct Selection (CS) is said to occur] be at least \( P^* \) (a prespecified constant between \((k)^{-1} \) and 1) whenever \( \theta[k-t+1] - \theta[k-t] \geq \delta^* \) \((\delta^* \) is a prespecified positive constant). A different procedure was proposed by Gupta (1956, 1965): rather than selecting the \( t \) populations associated with the \( t \) highest sample means, he selects a
subset of the k populations (retaining in the selected subset all the populations yielding sample means close to the t highest sample means) and requires that the probability be at least $P^*$ that the selected subset contains the t best (when this occurs, a CS is said to occur). Both Bechhofer and Gupta considered the case of normal distributions with common known variances; for the case of normal distributions but with (possibly different) unknown variances the reader is referred to Dudewicz and Dalal (1976). The robustness of the means procedure is broached in Lehmann (1963) and is under investigation, in a more general context, by one of the authors [YJL].

Lehmann (1963) and Bartlett and Govindarajulu (1968) based selection procedures on the joint ranks of the observations in the combined sample of $N = \sum n_i$ observations. Specifically, each observation $X_{ij}$ is assigned a score $a_{ij} = E[Z(R_{ij})|G]$ where $Z(1) < \ldots < Z(N)$ denotes an ordered sample from any continuous df $G$ and $R_{ij}$ denotes the rank of $X_{ij}$ in the combined sample. The selection procedures are then based on the quantities $n_i^{-1} \sum_j a_{ij}$ (1 $\leq i \leq k$). Lehmann's approach uses a Bechhofer-type (indifference-zone) approach while Bartlett and Govindarajulu use a Gupta-type (subset-selection) approach. Bartlett and Govindarajulu also base some selection procedures on randomized scores (i.e., quantities $n_i^{-1} \sum_j Z(R_{ij})$ (1 $\leq i \leq k$)); but we have shown (details will not be given
here) that in selection procedures based on randomized scores the probability of CS (denoted by P(CS)) is bounded away from 1 for any configuration of parameters and two different statisticians reach, with positive probability, two different conclusions from the same set of observations. This extends results of Jogdeo (1966) to ranking and selection problems. An extensive review of other selection procedures (including joint rank procedures) is provided in Lee and Dudewicz (1974).

The model usually assumed in the literature is that of the one-way analysis-of-variance model. The selection procedure investigated in this paper arises from the two-way analysis-of-variance type model where block effect enters: namely \( P(X_{ij} \leq x) = F(x - n_j - \theta_j) \) where \( n_j \) is a nuisance location parameter of the \( j \)th block \((1 \leq j \leq n)\). In this case ranks within each block are preferable to joint ranks. McDonald (1972, 1973) makes subset-selection approaches to a selection problem by basing terminal decision rules on ranks within each block, and Dudewicz and Fan (1973) suggested an indifference-zone approach. In Section 2 we investigate, by an indifference-zone approach, selection procedures based on ranks within each block (we denote this procedure by \( P_V \)) under the slipped parameter configuration (SPC) \( \theta_{[1]} \leq \ldots \leq \theta_{[k-t]} < \theta_{[k-t+1]} = \ldots = \theta_{[k]} \); all the results are asymptotic. In Section 3, we investigate the asymptotic relative efficiency (ARE) of \( P_V \) with respect to \( P_{MP} \) as \( \theta_{[k-t+1]} - \theta_{[k-t]} \) tends to zero under the SPC assumption. The configuration of \( \theta_i \)'s minimizing \( P(CS|P_V) \) is investigated in Section 4; in particular
we show that the SPC is not necessarily least-favorable. In Section 5 we discuss practicality of the assumption of the SPC as an underlying configuration. In this article we denote by $O(a)$ a positive quantity such that $a^{-1}O(a)$ converges to a positive constant in the limit of $a$.

2. $P[CS|p_v]$ under the SPC: Asymptotic Results

We make the following probability requirement for given $\delta^*$ and $P^*$ ($\delta^* > 0$, $P^* < 1$):

$$P[CS|p_v] > P^*$$ whenever $\theta_{[k-t+1]} - \theta_{[k-t]} \geq \delta^*$.

Consider the following single-stage procedure: Take $n$ independent vectors $X_j = (X_{1j}, \ldots, X_{kj})$ $(1 \leq j \leq n)$ ($X_{ij}$ denotes the $j$th observation from $\pi_i$); compute $H_i = \sum_{j=1}^{n} R_{ij}$ $(1 \leq i \leq k)$ where $R_{ij} = \# \text{ of } X_{i',j} \leq X_{ij} (1 \leq i' \leq k)$; and select (as being the $t$ best populations) the populations associated with the $t$ highest $H_i$'s (breaking ties, if any, by randomization).

We first consider $t = 1$ and then generalize to $t \geq 1$.

Let

$$\Omega_0 = \{\delta \in R_k; \delta = (\theta[1], \ldots, \theta[k])\},$$

$$\Omega_0(\delta^*, t) = \{\delta \in \Omega_0; \theta_{[k-t+1]} - \theta_{[k-t]} \geq \delta^*\},$$
Lemma 2.1: For selection of \( \pi(k) \) under \( \omega(\delta^*,1) \), \( P[CS|P_V] \) is a nondecreasing function of \( \theta_k \). Hence \( \inf_{\omega(\delta^*,1)} P[CS|P_V] = P[CS|P_V, \delta^*_0(1)] \).

Proof
See Theorem 3.1 of McDonald (1972).

Now we wish to determine a sample size \( n_\theta \) which will guarantee \( P[CS|P_V, \delta_0(\delta^*,1)] \) to be at least \( P^* \) for given \( \delta^* > 0 \), but we do not know how to determine the sample size for given \( P^* \) and \( \delta^* \). Rather, we find \( \delta^* \) for given \( P^* \) and sample size \( n \), namely we put \( \delta^* \) as a function of \( n \) and \( P^* \) and then solve \( n \) for given \( \delta^* \) and \( P^* \). (This method was introduced by Lehmann (1963).) To this end we need to investigate the asymptotic determination of \( P[CS|P_V] \) under the following configuration with \( t = 1 \):

\[
\hat{\sigma}_0(t,n): \theta[1] = \ldots = \theta[k-t], \quad \theta[k-t+1] - \theta[k-t] = \delta(n),
\]

\[
\theta[k-t+1] = \ldots = \theta[k].
\]

Let \( H(i) \) be the sum of rank scores yielded by \( \pi(i) \). To show the dependence of \( H(i) \) on \( n \), we write \( H(i)(n) \), and for the notational convenience, without loss of generality, we let
\[ \theta[i] = \theta_i, \quad \pi(i) = \pi_i, \quad \text{and thus} \quad H_i(n) = H_i(n) \quad (1 \leq i \leq k). \]

For large samples, since \( \lim_{n \to \infty} P[H_k(n) - H_i(n) = 0, \quad i \leq k-1 | \theta_0(n)] = 0 \),

we drop the randomization part of \( P[CS|P_V] \). Thus

\[
P[CS|P_V, \theta_0(1,n)] = P[H_k(n) - H_i(n) > 0, \quad 1 \leq i \leq k-1 | \theta_0(1,n)]
\]

(2.3)

\[
P[\frac{1}{\sqrt{n}}(H_k(n) - H_i(n)) > 0, \quad 1 \leq i \leq k-1 | \theta_0(1,n)]
\]

\( (A(x) \equiv B(x) \) means \( |A(x) - B(x)| \to 0 \) as \( x \) approaches a limit). We will approximate (2.3), and in the sequel we need the following.

Lemma 2.2: Let \( G(x) \) be an absolutely continuous function possessing a quadratically integrable derivative \( G'(x) \) and let \( f(x) \) be an absolutely continuous df with a pdf \( f(x) \). If \( \int H^2(x)f^2(x)dx < \infty \), then

\[
\lim_{h \to 0} \left| \frac{1}{h} \left( \frac{G(x+h)}{h} - G(x) \right) H(x)dF(x) - \int G'(x)H(x)dF(x) \right| = 0.
\]

(For the special case \( H(x) \equiv 1 \) and \( F(x) \equiv G(x) \) a.e., this is Lemma 3.4 of Mehra and Sarangi (1967).)

Proof

See Lemma 3.4 of Mehra and Sarangi (1967).•

Let

\[
\delta = \lim_{n \to \infty} n^{\frac{1}{2}} \delta(n), \quad \delta > 0 \quad \text{fixed}
\]

(the cases \( n^{\frac{1}{2}} \delta(n) \to \infty \) and \( n^{\frac{1}{2}} \delta(n) \to 0 \), as \( n \to \infty \), are covered after Theorem 2.5), and assume
(2.4) \[ \int f^2(x)dx < \infty \quad (f(x) \equiv \text{pdf of the underlying df } F). \]

(For some pdf's \( \int f^2(x)dx \) does not exist. Df's satisfying (2.4) are characterized by Lemma 1.4.1 of Kagan, Linnik and Rao (1973).)

Lemma 2.3: Under the configuration of \( \delta_0(1,n) \), defining
\[
V_i(n) = n^{-k}(H_k(n) - H_i(n)) \quad (1 \leq i \leq k-1),
\]
we find that
\[
(2.5) \quad \lim_{n \to \infty} E[V_i(n)] = \delta k \int f^2(x)dx \quad (1 \leq i \leq k-1),
\]
\[
(2.6) \quad \lim_{n \to \infty} \text{Var}[V_i(n)] = k(k+1)/6 \quad (1 \leq i \leq k-1),
\]
and
\[
(2.7) \quad \lim_{n \to \infty} \text{Cov}[V_i(n), V_{i'}(n)] = k(k+1)/12 \quad (1 \leq i \neq i' \leq k-1).
\]

Proof
Defining
\[
P_r(i) = P[X_{r1} \text{ has the } r^{th} \text{ rank among } X_{11}, \ldots, X_{kl} | \delta_0(1,n)],
\]
we have
\[
(2.8) \quad E[V_i(n)] = n^{-k} \sum_{j=1}^{n} E(R_{kj} - R_{ij}) = n^{1/2} \sum_{r=1}^{k} r(P_r^{(k)} - P_r^{(i)}).
\]

Let \( \theta_1 = \ldots = \theta_{k-1} = \theta \) and \( \theta_k = \theta + \delta(n) \).
\[ p^{(k)}_{r} = \frac{(k-1)}{r-1} \int r^{r-1}(x-\delta)[1 - F(x-\delta)]^{k-r} dF(x-\delta) \]

\[ = \frac{(k-1)}{r} \int f^{r-1}(x-\delta)[1 - F(x-\delta)]^{k-r} dF(x-\delta). \]

Note that we do not lose any generality by letting \( \theta = 0 \).

Now

\[ p^{(k)}_{r} = \frac{(k-2)}{r-2} \int f^{r-1}(x+\delta(n))[1 - 1(x + \delta(n))]^{k-r} dF(x) \]

\[ + \frac{(k-2)}{r-1} \int f^{r-1}(x+\delta(n))[1 - F(x + \delta(n))]^{k-r} dF(x), \]

\[ p^{(i)}_{r} = \frac{(k-2)}{r-2} \int f^{r-2}(x)[1 - F(x)]^{k-r} dF(x) \]

\[ + \frac{(k-2)}{r-1} \int f^{r-1}(x)[1 - F(x)]^{k-r-1}[1 - F(x - \delta(n))] dF(x), \]

and combining \( p^{(k)}_{r} \) and \( p^{(i)}_{r} \) and taking the limit yields

\[ \lim_{n \to \infty} n^{(k)(i)}_{r} = \frac{(k-1)}{r-1} \delta \int \frac{d}{dx} f^{r-1}(x)[1 - F(x)]^{k-r} dF(x) \]

\[ + \frac{(k-2)}{r-2} \int f^{r-2}(x)[1 - F(x)]^{k-r} f^2(x) dx \]

\[ - \frac{(k-2)}{r-1} \int f^{r-1}(x)[1 - F(x)]^{k-r-1} f^2(x) dx, \]

hence (2.5) is obtained from (2.8). Define

\[ p^{(i,j)}_{l,q} = \left[ X_{il} \text{ has the } i^\text{th} \text{ rank, and } X_{jl} \text{ has the } j^\text{th} \text{ rank among } X_{1l}, \ldots, X_{kl} \right] \]
Note that \( P_{\ell,k}(i,j) = 0 \) \((i \neq j, 1 \leq \ell \leq k)\).

Then

\[
\lim_{n \to \infty} P_r(i) = \frac{1}{k}, \quad \text{and} \quad \lim_{n \to \infty} P_{\ell,q}(i,j) = \frac{1}{k(k-1)}.
\]

(For details see Lee and Dudewicz (1974).) From (2.10), a computation shows (2.6) and (2.7).

Thus we have obtained asymptotic moments of \( V_i(n) \) \((1 \leq i \leq k-1)\). To evaluate \( P[CS| P_V, \delta_0(1,n)] \), we need to obtain an asymptotic distribution of \( V(n) = (V_1(n), \ldots, V_{k-1}(n))' \).

We can show that any linear combination of \( (V_1(n), \ldots, V_{k-1}(n))' \) has an asymptotic normal distribution by a Lindeberg-Feller type central limit theorem (specifically see §26 of Gnedenko and Kolmogorov (1949)). Thus \( V(n) \) has an asymptotic \((k-1)\)-variate normal distribution with certain known mean and variance-covariance. The following lemma is proven in Lee and Dudewicz (1974).

**Lemma 2.4:** The \((k-1)\)-variate random vector \((V_1(n), \ldots, V_{k-1}(n))'\) has an asymptotic \((k-1)\)-variate normal distribution with mean \( \delta k \int f^2(x)dx \) and variance-covariance

\[
\sigma_{ij} = \frac{k(k+1)(1 + \delta_{ij})}{12}
\]

where \( \delta_{ij} = \begin{cases} 
1 & \text{if } i = j \\
0 & \text{otherwise.} 
\end{cases} \)
Now we are prepared to approximate $P[CS|P_V, \hat{\theta}_0(1,n)]$. Let $(U_1, \ldots, U_{k-1})'$ be a $(k-1)$-variate normal random vector satisfying $E(U_i) = 0$, $\sigma_{ij} = (1 + \delta_{ij})/2$. Then

$$P[CS|P_V, \hat{\theta}_0(1,n)]$$

$= P\{[k(k+1)/6]^{-1/2}[V_i(n) - \delta k \int f^2(x)dx]$

$> -[k(k+1)/6]^{-1/2} \delta k \int f^2(x)dx, \ 1 \leq i \leq k-1|\hat{\theta}_0(1,n)\}$

$= P\{U_i > -[k(k+1)/6]^{-1/2} \delta k \int f^2(x)dx, \ 1 \leq i \leq k-1\}$.

Letting $\Delta > 0$ satisfy

$$P(U_i > -\Delta, \ 1 \leq i \leq k-1) = P^\#$$

we find

Theorem 2.5: For $P[CS|P_V, \hat{\theta}_0(1,n)]$ to be asymptotically $P^\*$ ($1/k < P^\* < 1$), $\delta(n)$ should satisfy

$$\lim_{n \to \infty} n^{1/2} \delta(n) = [k(k+1)/6]^{1/2} \Delta$$

We make several remarks on implications of Theorem 2.5:

(i) if $\lim_{n \to \infty} n^{1/2} \delta(n) = 0$, then $\lim_{n \to \infty} P[CS|P_V, \hat{\theta}_0(1,n)] = 1$,

and if $\lim_{n \to \infty} n^{1/2} \delta(n) = 0$, then $\lim_{n \to \infty} P[CS|P_V, \hat{\theta}_0(1,n)] = 1/k$,

that is if $\delta(n) \propto 0(n^{-1/2})$, then $P[CS|P_V, \hat{\theta}_0(1,n)]$ converges either to 1 or $1/k$, in which case we cannot relate $n$ and $\delta^\*$ (as $\delta^* \to 0$) for fixed $P^\*$ (for the cases of
\(P_{\text{MP}}\) and joint rank procedures (i) is implicit in Lehmann (1963);

(ii) when \(\delta(n) = O(n^{-\frac{1}{2}})\), we can relate \(n\) and \(\delta^*\) for given \(P^*\) via \(n_A(P) \equiv \text{approximated } n\)

\[
n_A(P) = (\Delta/\delta^*)^2[k(k+1)/6][k \int f^2(x)dx]^{-2};
\]

(iii) consider the question how good \(n_A(P)\) is; namely letting \(n_{\text{TRUE}}\) denote the sample size which will guarantee \(P[CS|P, \theta_0(1)] \geq P^*\), does \(n_A(P)/n_{\text{TRUE}}\) converge to 1 as \(\delta^* \to 0\)?; the answer is conjectured to be affirmative (see Lee and Dudewicz (1974)); and

(iv) the conjecture of (iii) justifies, in part, dropping the randomization part of \(P[CS|P, \theta_0(1,n)]\) as we did earlier. [Such dropping has been done without justification in the literature, e.g., p. 270 of Lehmann (1963), p. 295 of Puri and Puri (1968), p. 623 of Puri and Puri (1969), p. 377 of Bapkar and Gore (1971), and p. 258 of Alam and Thompson (1971) among others.]

The \(P_{\text{MP}}\) version of (2.12) is due to Lehmann (1963). Namely, let \(m\) be the sample size for \(P[CS|P_{\text{MP}}, \theta_0(1,m)] = P^*\) asymptotically. Then

\[
m = 2(\Delta \sigma/\delta^*)^2
\]

where \(\sigma^2\) is the variance of the underlying df, \(\Delta\) satisfies (2.11), and \(\delta^* = \theta[k] - \theta[k-1]\). [(2.13) is the equation (11) of Lehmann (1963).] Note that when the underlying df is normal,
(2.13) is the sample size obtained by Bechhofer (1954), and is thus exact.

The results in this section apply so far only to the selection of the best population under \( \hat{\theta}_0(1) \), but can be extended to the \( t \) best selection problem under configuration \( \hat{\theta}_0(t) \).

The proof is, of course, more complicated so we will state the results corresponding to Lemma 2.4 and Theorem 2.5 and refer to Lee and Dudewicz (1974) for proofs. We have

\[
(2.14) \quad P[C_{St}_1 ; P_y, \hat{\theta}_0(t,n)]
\]

\[
= P[H_{z_i}(n) - H_i(n) > 0, \quad k-t+1 \leq \ell \leq k, \quad 1 \leq i \leq k-t]
\]

\[
= P[V_{z_i}(n) > 0, \quad k-t+1 \leq \ell \leq k, \quad 1 \leq i \leq k-t]
\]

where

\[
V_{z_i}(n) = n^{-\frac{1}{2}}(H_{z_i}(n) - H_i(n)) \quad (k-t+1 \leq \ell \leq k, \quad 1 \leq i \leq k-t).
\]

**Lemma 2.6:** \((V_{k-t+1,n}(n), \ldots, V_{k-t+1,k-t}(n), \ldots, V_{k,k-t}(n))'\) is a \( t(k-t) \)-variate random vector the limiting distribution of which, under the configuration \( \hat{\theta}_0(t,n) \), is the distribution of a \( t(k-t) \)-variate normal vector \((U_{z_i}; k-t+1 \leq \ell \leq k, \quad 1 \leq i \leq k-t)'\) with

\[
E(U_{z_i}) = \delta k \int f^2(x)dx, \quad Var(U_{z_i}) = k(k+1)/6, \quad Corr(U_{z_i}, U_{z_i}) = Corr(U_{z_i}, U_{z_i}') = 1/2, \quad Corr(U_{z_i}, U_{z_i}') = 0, \quad (k-t+1 \leq \ell \leq k, \quad 1 \leq i \neq i' \leq k-t),
\]

where \( \delta = \lim_{n \to \infty} n^{1/2} \delta(n) \).
Let \((U_1, \ldots, U_{k-t}, W_{k-t+1}, \ldots, W_{k-1})'\) be a \((k-1)\)-variate normal random vector with \(E(U_i) = E(W_j) = 0, \ Var(U_i) = Var(W_j) = 1, \ Corr(U_i, U_{i'}) = Corr(W_j, W_{j'}) = 1/2, \ Corr(U_i, W_j) = -1/2 \ (1 \leq i \neq i' \leq k-t, \ k-t+1 \leq j \neq j' \leq k)\), and let \(\Delta_t > 0\) satisfy

\[
(2.15) \quad P^* = P[U_i > -\Delta_t, W_j > 0, 1 \leq i \leq k-t, k-t+1 \leq j \leq k].
\]

**Theorem 2.7:** For (2.14) to be \(P^* \ (1/(k_t) < P^* < 1)\) asymptotically under \(\delta_0(t, n)\), \(\delta(n)\) should satisfy

\[
(2.16) \quad \delta = \lim_{n \to \infty} n^4 \delta(n) = [k(k+1)/6]^2 [k \int f^2(x) dx]^{-1} \Delta_t.\]

The implications of Theorem 2.7 are the same as those of Theorem 2.5. Therefore through Theorem 2.7, we can relate \(n\) to \(\delta^*\) and \(P^*\) by

\[
(2.17) \quad n_{A}^*(P_V) = (\Delta_t/\delta^*)^2 (k(k+1)/6) [k \int f^2(x) dx]^{-2}
\]

(note the difference between \(\Delta_t\) and \(\Delta_t\) in (2.12) and (2.17)).

The \(P_{MP}\) equivalent of (2.16) is due to Puri and Puri (1969) and is

\[
(2.18) \quad m = 2(\Delta_t \sigma/\delta^*)^2
\]

where \(m\) is the sample size for \(P[CS|P_{MP}, \delta_0(t, m)]\) to be \(P^*\), \(\sigma^2\) is the variance of the underlying df, and \(\Delta_t\) satisfies (2.15). (2.18) is the equation (4A.11) of Puri and Puri (1969).
In this section we have studied $P[CS|P_V]$ under the SPC; namely how to relate the necessary sample size to the minimum discrepancy worth detecting and the required $P[CS]$ for large sample size under the assumption that the underlying df is known. Similar results for joint rank procedures were obtained by Lehmann (1963) and Puri and Puri (1969).

3. ARE of $P_V$ under the SPC.

Suppose there are two different selection procedures $P_1$ and $P_2$ with the same probability requirement. We define an asymptotic relative efficiency (ARE) of $P_1$ with respect to $P_2$ as

$$\text{ARE}(P_1, P_2) = \lim_{\delta^* \to 0} \left( \frac{\text{Sample size for } P_2}{\text{Sample size for } P_1} \right).$$

To determine the ARE this way, we should be able to determine a sample size for given $\delta^*$ and $P^*$. We noted that when we let $\delta^* = \delta(n)$, and $\lim_{n \to \infty} n^{1/2} \delta(n) = c$ (an appropriate constant), $P[CS]$ converges to $P^*$ as $n \to \infty$. In other words, by letting $n = n(\delta^*)$ and requiring $\lim_{\delta^* \to 0} [n(\delta^*)]^{1/2} \delta^*$ to converge to some constant, $P[CS]$ converges to $P^*$ as $\delta^* \to 0$. Thus letting $n_{P_i}(\delta^*)$ (i = 1, 2) (the selection sample size for $P_i$ for a given $\delta^*$) satisfy $\lim_{\delta^* \to 0} [n_{P_i}(\delta^*)]^{1/2} \delta^* = c_i$ (i = 1, 2), we can determine the ARE($P_1, P_2$) (as $\delta^* \to 0$). One may suspect that $\text{ARE}(P_1, P_2)$ (as $\delta^* \to 0$) and $\text{ARE}(P_1, P_2)$ (as $n_{P_2} \to \infty$) may be different. [Note that the latter quantity was used by Lehmann (1963)
to compute the ARE of a joint rank procedure with respect to $P_{MP}$. However we can show their equivalence as follows. If for given $P^*$ and $n_{P_i} (i=1,2)$ $\delta(n_{P_i})$ is determined so that $\lim n_{P_i}^{1/2} \delta(n_{P_i}) = c_i (i=1,2)$, then $P[CS|P_i] \equiv P^*$. 

But since $P_1$ and $P_2$ are required to satisfy the same probability requirement, we have $\delta(n_{P_1}) = \delta(n_{P_2})$, and also $\lim n_{P_1}^{1/2} \delta(n_{P_1}) = c_1$ and $\lim n_{P_2}^{1/2} \delta(n_{P_2}) = c_2$. Note that as $n_{P_2} \to \infty$, $\delta(n_{P_2}) = \delta(n_{P_1}) \to 0$ and thus $n_{P_1} \to \infty$.

Therefore we have

$$\text{(3.2)} \quad \text{ARE}(P_1, P_2) = \text{ARE}(P_1, P_2) = \text{ARE}(P_1, P_2),$$

$$\delta^* \to 0 \quad \delta(n_{P_1}) = \delta(n_{P_2}) \to 0 \quad n_{P_2} \to \infty$$

By combining (2.17) and (2.18), we can compute the ARE($P_V, P_{MP}$) (as $\delta^* \to 0$) under $\delta_0(t)$:

$$\text{(3.3)} \quad \text{ARE}(P_V, P_{MP}) = 12k \sigma^2 \left[ \int f^2(x)dx \right]^2 / (k+1).$$

This ARE($P_V, P_{MP}$) is tabulated in Table 3.1 for several df's.

* The lower bound for $12\sigma^2 \left[ \int f^2(x)dx \right]^2$ was obtained by Hodges and Lehmann (1956) for the location parameter case.
Hodges and Lehmann (1962) aligned observations so that they are free of block effects, and applied joint-rank procedures to random block designs. Likewise we can align observations, apply joint-rank selection procedures, and thus obtain better efficiencies (in the order of \((k+1)/k\)). But there are cases where alignments of block effects are not applicable, e.g. p. 485 of Hodges and Lehmann (1962).

In passing we can note that Lehmann's lemma (Lemma 1 of Lehmann (1963)) which leads to (2.13) (and hence to (2.18) as well), is only justified heuristically. We now give a proof. We need the following generalized Helly-Bray Lemma:

**Lemma 3.1:** (Generalized Helly-Bray Lemma). Let \(Q_n \to Q\), a continuous df of a random variable, and let \(\{g_n\}, g, h\) be continuous functions satisfying

(i) \(|g_n(x)| \leq h(x)\) for all \(x\)

(ii) \(g_n(x) + g(x)\) uniformly on finite intervals, and

(iii) \(\int h \, dQ_n \to \int h \, dQ\).

Then \(\int g_n \, dQ_n \to \int g \, dQ\).

**Proof**

Theorem 3.2: (Lemma 1 of Lehmann (1963).) Let $\Delta$ satisfy (2.11) and let $\bar{X}(i)$ be a sample mean (based on the sample size $n$) yielded by $\pi_i$ (the population associated with $\theta_i$), and let $\sigma^2$ be a variance of the underlying df $F$ with a pdf $f$. Under the configuration $\theta_0(1,n)$, if $\lim n^{\frac{1}{2}}\delta(n) = 2^{\frac{1}{2}}A\sigma$, then we have

$$\lim_{n \to \infty} P[\bar{X}(k) \geq \bar{X}(i), 1 \leq i \leq k-1 | \theta_0(1,n)] = P^h.$$

Proof

Let $\lim n^{\frac{1}{2}}\delta(n) = \delta (> 0)$. Assuming, without loss of generality, that $E(X(i)) = \theta_i$,

$$\lim_{n \to \infty} P[\bar{X}(k) \geq \bar{X}(i), 1 \leq i \leq k-1 | \theta_0(1,n)] = \lim_{n \to \infty} P \left[ \frac{\bar{X}(k) - \theta[k]}{\sigma/\sqrt{n}} \geq \frac{\bar{X}(i) - \theta[i]}{\sigma/\sqrt{n}} - \frac{\theta[k] - \theta[i]}{\sigma/\sqrt{n}}, 1 \leq i \leq k-1 \right].$$

Let $Y_i(n) = \frac{n^{\frac{1}{2}}(X(i) - \theta(i))}{\sigma}$ (1 $\leq i \leq k-1$) and let $Y_i(n)$ be distributed as $F_n(\cdot)$. Then since the second moment of the underlying df exists, $F_n(y)$ converges to $\Phi(y)$ uniformly for all $y$ as $n \to \infty$, where $\Phi(y) = \int_{-\infty}^{y} (2\pi)^{-\frac{1}{2}} \exp[-x^2/2]dx$.

Thus for every given $\varepsilon > 0$ there exists an integer $n_1(\varepsilon)$ such that, whenever $n \geq n_1(\varepsilon)$,

$$|F_n(y + \delta/\sigma) - \Phi(y + \delta/\sigma)| < \varepsilon/2.$$

Now by the continuity assumption there exists an integer $n_2(\varepsilon)$
such that, whenever \( n \geq n_2(\varepsilon) \),

\[
\max \left( \int_{y \in (\delta/\sigma, n^{1/2}\delta(n)/\sigma)} dF_n(y) , \int_{y \in (n^{1/2}\delta(n)/\sigma, \delta/\sigma)} dF_n(y) \right) < \varepsilon/2.
\]

Hence, for all \( n \geq \max (n_1(\varepsilon), n_2(\varepsilon)) \),

\[
|F_n(y + n^{1/2}\delta(n)/\sigma) - \Phi(y + \delta/\sigma)| < \varepsilon.
\]

Therefore we have

\[
\phi^{k-1}(x + \delta/\sigma),
\]

and hence

\[
\lim_{n \to \infty} P[\bar{X}_k(n) \geq \bar{X}_i(n), 1 \leq i \leq k-1 | \delta_0(1,n)]
\]

\[
= \lim_{n \to \infty} P[Y_k(n) \geq Y_i(n) - n^{1/2}\delta(n)/\sigma, 1 \leq i \leq k-1]
\]

\[
= \lim_{n \to \infty} \int \left[ \prod_{i=1}^{k-1} F_n(y + n^{1/2}\delta(n)/\sigma) \right] dF_n(y)
\]

\[
= \int \phi^{k-1}(x + \delta/\sigma) d\Phi(x).
\]

The last equality is due to the generalized Helly-Bray Lemma. Thus letting \( \delta = 2^{1/2}\Delta \sigma \), where \( \Delta \) satisfies (2.11), the Theorem follows. \( \blacksquare \)

Note that if \( \delta = 0 \) or \( \infty \), then

\[ P[\bar{X}_k(n) > \bar{X}_i(n), 1 \leq i \leq k-1 | \delta_0(1,n)] \]

converges to \( 1/k \) or \( 1 \) respectively.
4. LFC and Counterexamples.

The configuration of $\theta_i$'s which minimizes $P[CS]$ for any given selection procedure is called the least-favorable configuration (LFC). The SPC, $\hat{\delta}_0(t)$, is often least-favorable for selection procedures in the indifference-zone approach, and the equal-parameter configuration (EPC) $\theta[1] = \ldots = \theta[k]$ is often least-favorable in subset-selection approaches.

Rizvi and Woodworth (1970) showed that

$$\inf_{\Omega_0} P[CS] < P[CS|\hat{\delta}_0(t)]$$

for selection procedures based on joint ranks in the indifference-zone approach (the subset-selection approach) for some df's. And McDonald (1972) also showed that

$$\inf_{\Omega_0} P[CS] < P[CS|EPC]$$

for one of his subset-selection procedures based on vector ranks. In this section the counterexamples of Rizvi and Woodworth (1970) are modified to show that the SPC, $\hat{\delta}_0(t)$, is not the LFC for $P_V$. We consider two counterexamples: first, for the case of fixed $\delta^*$ and finite $n$; and second, for the case of $\delta^* \to 0$ (and thus $n \to \infty$).

Counterexample 4.1: Let $k = 3$, $t = 1$ and $F$ be a continuous df which places probabilities of $q$ and $p (= 1 - q)$ uniformly on the intervals $(0, \varepsilon)$ and $(1, 1 + \varepsilon)$ respectively, where $\varepsilon (< 1/3)$ is a positive constant. Let $\delta^* = \varepsilon$, $0 \leq \delta_2 \leq \delta^*$, and $\hat{\delta}(\delta_2) = (\theta_1, \theta_2, \theta_3) = (0, \delta_2, \delta_2 + \delta^*)$, where $\theta_i$ is the location parameter for $\pi_i$ ($i = 1, 2, 3$). Then for $n = 1$ $P[CS|P_V, \hat{\delta}(\delta_2)]$ is a constant for any $\delta_2$ and for $n = 2$...
max \( P[CS|p_\gamma, \hat{\delta}(\delta_2)] = P[CS|p_\gamma, \hat{\delta}(0)] \) and \( \min \ P[CS|p_\gamma, \hat{\delta}(\delta_2)] = P[CS|p_\gamma, \hat{\delta}(\delta^*)] \).

This constitutes a counterexample because \( \hat{\delta}(0) = (0,0,\delta^*) \) is a SPC while \( \hat{\delta}(\delta^*) = (0,\delta^*,2\delta^*) \) is not.

Proof

The supports of the distribution of the populations under the parameter configuration \( \hat{\delta}(\delta_2) \) can be depicted as in Figure 4.1, where "heights" show the supports of df's under \( \hat{\delta}(\delta_2) \).

Figure 4.1 Supports of df's under \( \hat{\delta}(\delta_2) \)

\[
\begin{array}{c|c|c|c|c|c|c|c}
\pi_1 & \pi_2 & \pi_3 \\
\hline
\delta_2 & \delta^* & 2\delta^* & 3\delta^* & 1 & 1+\delta^* & 1+2\delta^* & 1+3\delta^* \\
\end{array}
\]

Note that \( \pi_3 \) (the best population) is separated from \( \pi_1 \) and \( \pi_2 \) in its support while \( \pi_1 \) and \( \pi_2 \) do not have disjoint supports.

Fix \( n = 2 \). Let \( B_i \) be 0, 1, or 2 according as 0, 1, or 2 observations from \( \pi_i \) are in the upper interval of the support of its distribution, let \( B = (B_1, B_2, B_3) \), and let \( b = (b_1, b_2, b_3) \) be a realization of \( B \). Clearly \( P[B=b|\theta_1, \theta_2, \theta_3] = \prod_{i=1}^{3} p_i^{b_i} q_i^{1-b_i} \).

Let \( R = \begin{pmatrix} R_{11} & R_{12} & R_{13} \\ R_{21} & R_{22} & R_{23} \end{pmatrix} \) be the matrix of ranks each row of which is a row vector of ranks \( R_{ij} = 1,2,3 \) and let...
\( r = \begin{pmatrix} r_{11} & r_{12} & r_{13} \\ r_{21} & r_{22} & r_{23} \end{pmatrix} \) be a typical realization of \( R \). Given \( R = r \) a CS (selection of \( \pi_3 \)) occurs with probability 1 if 

\[ r_{13} + r_{23} > \max(r_{12} + r_{22}, r_{11} + r_{21}) \]

with probability \( \frac{1}{2} \) if 

either \( r_{13} + r_{23} = r_{12} + r_{22} > r_{11} + r_{21} \) or \( r_{13} + r_{23} = r_{11} + r_{21} > r_{12} + r_{22} \),

with probability \( \frac{1}{3} \) if \( r_{13} + r_{23} = r_{11} + r_{21} = r_{12} + r_{22} \), and 

with probability 0 otherwise. The conditional probability that \( R = r \) given \( B = b \) under \( \delta(\delta_2) \) involves 27 possible rank combinations. Many of the possible rank combinations are not equally likely (hence our situation differs from those of Rizvi and Woodworth (1970) and McDonald (1972), where the rank combinations are equally likely). One example of the computations is that of \( P[CS|P_Y, \delta(\delta_2), B=b] \) for \( b = (0, 1, 1) \). \( b = (0, 1, 1) \) means that for \( \pi_1 \) both observations are from the lower support, and for \( \pi_2 \) and \( \pi_3 \) one of two observations is from the upper support; this can be expressed as:

(i) \( \begin{pmatrix} [0, \delta^*], & [\delta_2, \delta_2 + \delta^*] & [\delta_2 + \delta^*, \delta_2 + \delta^* + \delta^*] \\ [0, \delta^*], & [1 + \delta_2, 1 + \delta_2 + \delta^*] & [1 + \delta_2 + \delta^*, 1 + \delta_2 + \delta^* + \delta^*] \end{pmatrix} \)

and

(ii) \( \begin{pmatrix} [0, \delta^*], & [1 + \delta_2, 1 + \delta_2 + \delta^*], & [\delta_2 + \delta^*, \delta_2 + \delta^* + \delta^*] \\ [0, \delta^*], & [\delta_2, \delta_2 + \delta^*] & [1 + \delta_2 + \delta^*, 1 + \delta_2 + \delta^* + \delta^*] \end{pmatrix} \)

express supports from which observations for each population originate to have \( b = (0, 1, 1) \). Given (i) there are two possible rank combinations, while given (ii) there are two other possibilities. We now compute the probability of each rank combination. Let \( \delta_1 = \delta^* - \delta_2 \). Then
\[
P\left[\begin{pmatrix} 1, 2, 3 \end{pmatrix} \right] = \{ P[0<X_1<\delta_2, \delta_2<X_2<\delta_2+\delta^*, \delta_2+\delta^*<X_3<\delta_2+2\delta^*] \\
+ P[\delta_2<X_1<\delta^*, \delta_2<X_2<\delta^*, \delta_2+\delta^*<X_3<\delta_2+2\delta^*] \\
+ P[\delta_2<X_1<\delta^*, \delta^*<X_2<\delta_2+\delta^*, \delta_2+\delta^*<X_3<\delta_2+2\delta^*] \\
x P[0<X_1<\delta^*, 1+\delta_2<X_2<1+\delta_2+\delta^*, 1+\delta_2+\delta^*<X_3<1+\delta_2+2\delta^*] \\
= q^4 p^2 (1-\delta_1^2/2\delta^*2).
\]

Similarly

\[
P\left[\begin{pmatrix} 2, 1, 3 \end{pmatrix} \right] = q^4 p^2 \delta_1^2/2\delta^*2, \\
P\left[\begin{pmatrix} 1, 3, 2 \end{pmatrix} \right] = q^4 p^2 (1-\delta_1^2/2\delta^*2), \text{ and} \\
P\left[\begin{pmatrix} 2, 1, 3 \end{pmatrix} \right] = q^4 p^2 \delta_2^2/2\delta^*2.
\]

Thus

\[
P[CS|P_V, \delta(\delta_2), b=(0, 0, 1)] = 3/4 + \delta_1^2/(8\delta^*2).
\]

For the other cases the method of computation is similar. In all but 9 cases, \( P[CS|P_V, \delta(\delta_2), b] \) equals \( P[CS|P_V, \delta(\delta^*), b] \); those 9 cases are listed in Table 4.1. Now

\[
P[CS|P_V, \delta(\delta_2)] - P[CS|P_V, \delta(\delta^*)] \\
= \left[1 - \delta_1^2/(2\delta^*2)\right] \delta_1^2/(2\delta^*2) \left[ (4/3) q^4 p^2 + (4/3) q^3 p^3 + (4/3) q p^5 \right] > 0,
\]

and the difference is monotone increasing in \( \delta_2 \) for \( 0 \leq \delta_1 \leq \delta^* \) (namely monotone decreasing in \( \delta_2 \) for \( 0 \leq \delta_2 \leq \delta^* \)). Thus we conclude that \( P[CS|P_V, \delta(\delta_2)] \) is maximized at \( \delta(0) \) (which is
a SPC) and is minimized at $\delta(\delta^*)$. The case of $n=1$ is trivial and the Counterexample follows.

Table 4.1 *

| b   | \(P[B=b]\) | \(P[CS|P_V, B=b, \delta(\delta_2)]\) |
|-----|----------|----------------------------------|
| (0,1,0) | 2q^5p | 1/2 + $\delta_1^2/(4\delta^2)$ |
| (0,1,1) | 4q^4p^2 | 3/4 + $\delta_1^2/(8\delta^2)$ |
| (1,0,0) | 2q^5p | 1 - $\delta_1^2/(4\delta^2)$ |
| (1,0,1) | 4q^4p^2 | 1 - $\delta_1^2/(8\delta^2)$ |
| (1,1,0) | 4q^4p^2 | 1/6 + 1/3[1 - $\delta_1^2/(2\delta^2)]/\delta_1^2/(2\delta^2)]$ |
| (1,1,1) | 8q^3p^3 | 3/4 + 1/6[1 - $\delta_1^2/(2\delta^2)]/\delta_1^2/(2\delta^2)]$ |
| (1,2,1) | 4q^2p^4 | 1/4 + 5/24(\delta_1^2/\delta^2) |
| (2,1,1) | 4q^2p^4 | 2/3 - 5/24(\delta_1^2/\delta^2) |
| (2,2,1) | 2qp^5 | 2/3(1 - $\delta_1^2/\delta^2)]/\delta_1^2/(2\delta^2)]$ |

* Note that $\delta = \delta^*$ and $\delta_1 = \delta^* - \delta_2$. ■

We now show that the SPC is not the LFC for \(P_V\) even for large samples. One method of showing this is to show that the ratio of \(P[CS|P_V]\) under a configuration different from the SPC to that under the SPC converges to some number smaller than 1 for fixed $\delta^*$ as $n \to \infty$. Another method of constructing a counterexample is to show that the ratio of sample size for a configuration different from the SPC to that for the SPC converges to some number smaller than 1 for fixed $\delta^*$ as $P^* \to 1$. However we have obtained a counterexample by another method
originated by Rizvi and Woodworth (1970): we show that when the relation between \( n \) and \( \delta(n) = \theta_{[k-t+1]} - \theta_{[k-t]} \) satisfies (2.16), \( P[CS|P_V] \) converges (as \( n \to \infty \)) to some number smaller than \( P^* \) under a certain configuration of \( \theta_i \)'s different from the SPC, \( \mathcal{F}_0(t) \), but still in \( \Omega_0(\delta^*, t) \). This serves our purpose, because when the relation (2.16) holds between \( \delta(n) \) and \( n \), \( P[CS|P_V] \) converges, as \( n \to \infty \), to \( P^* \) under the SPC. [One may ask how much larger \( P[CS|P_V] \) is under the SPC than under the configuration we will consider; this question is discussed in the next section.]

Consider the selection of the \( t \) best populations, when the underlying df is a logistic distribution with a location parameter. For simplicity take \( k \geq 4 \) (\( k \) even) and \( t = k/2 \). Without loss of generality drop [ ] around the ordered parameter values for convenience of notation; namely take

\[
\theta[i] = \theta_i, \quad \pi(i) = \pi_i, \quad \text{and thus } H_{(i)}(n) = H_i(n) \quad (1 \leq i \leq k).
\]

Lemma 4.2: Let \( F(x) = (1+e^{-x})^{-1} \) and let

\[
\hat{\theta}_1(t, n); \quad \theta_1 = \ldots = \theta_{k-t-1} = -\theta_0, \quad \theta_{k-t} = 0, \quad \theta_{k-t+1} = \delta(n),
\]

\[
\theta_{k-t+2} = \ldots = \theta_k = \theta_0,
\]

where \( \delta(n) > 0 \) and is in the order of \( O(n^{-1/2}) \), \( \theta_0 > 0 \) fixed satisfying \( \theta_0 > \delta(n) \), and \( k = 2t \). Then

\[
(4.1) \quad \lim_{n \to \infty} P[CS|P_V, \hat{\theta}_1(t, n)] \leq \phi[A_t \rho((k+1)/k)^{1/2}]
\]

where \( A_t \) satisfies (2.15),
\begin{align}
(4.2) \quad \rho &= \left(3^\frac{k}{2} \int H_0(2F-1)dF\right) / \left\{ \int H_0^2dF - \left( \int H_0 dF \right)^2 \right\}^{\frac{k}{2}}, \\
(4.3) \quad H_0(x) &= (k-t-1)F(x-\theta_0) + 2F(x) + (t-1)F(x+\theta_0),
\end{align}

and

\[ \lim_{n \to \infty} n^{\frac{k}{2}} \delta(n) = [k(k+1)/6] \Delta \left( \int k f^2(x)dx \right)^{-1}. \]

Proof

For large samples, dropping the randomization part we have

\begin{align}
(4.4) \quad P[CS|P_V, \delta_1(t,n)] = P[ \max_{1 \leq i \leq k-t} H_i(n) < \min_{k-t < j \leq sk} H_j(n) ] \\
&\leq P[V(n) > 0 \mid \delta_1(t,n)],
\end{align}

where

\[ V(n) = n^{-\frac{k}{2}}(H_{k-t+1}(n) - H_{k-t}(n)). \]

We will find an upper bound for (4.4) as \( n \to \infty \) by finding \( \lim E[V(n)] \) and \( \lim \text{Var}[V(n)] \), and applying a Lindeberg-Feller type central limit theorem. The computations for \( E[V(n)] \) and \( \text{Var}[V(n)] \) are lengthy, and thus are omitted. In the limiting process using Olshen's lemma (Lemma (12) of Olshen (1967)), we have

\[ \lim_{n \to \infty} E[V(n) \mid \delta_1(t,n)] = [6(k+1)/k]^{\frac{k}{2}} \Delta \int H_0(x)[2F(x)-1]dF(x), \]

where \( H_0(x) \) is given by (4.3), and \( 0 < \theta_0 \leq C(k,t,F) \)

\begin{align}
(4.5) \quad \lim_{n \to \infty} \text{Var}[V(n) \mid \delta_1(t,n)] &= 2\left[ \int H_1^2dF - \left( \int H_1 dF \right)^2 \right].
\end{align}
and \( t \geq 2 \), where \( H_1 = (k-t-1)F(x+\theta_0) + 2F(x) + (t-1)F(x-\theta_0) \).

Since we assume \( k = 2t \), we have \( H_1 = H_0 \). Thus from (4.4)

\[
\lim_{n \to \infty} P[C|_{P_Y}, \hat{\theta}_1(t,n)] \leq \lim_{n \to \infty} P[V(n) > 0 | \hat{\theta}_1(t,n)]
\]

\[
= \lim_{n \to \infty} P\left( \frac{V(n) - \lim E[V(n)]}{\lim \sqrt{Var[V(n)]}} \geq \frac{\lim E[V(n)]}{\lim \sqrt{Var[V(n)]}} \right)
\]

\[
\leq \Phi[\Delta_p((k+1)/k)^{1/2}],
\]

where the last inequality is due to the asymptotic normality of \( \{V(n) - \lim E[V(n)]\}/(\lim Var[V(n)])^{1/2} \) due to a Lindeberg-Feller type central limit theorem and (4.5).

**Lemma 4.3:** For any \( k \) and \( t \), \( 1 \leq t < k \),

\[
\lim_{P^t \to 1} \phi^{-1}(P^t)/\Delta_t = 1
\]

where \( \Delta_t \) satisfies (2.15).

**Proof**

This follows from Lemma 2 of Rizvi and Woodworth (1970) upon noting that \( \Delta_t \), which satisfies (2.15), also satisfies

\[
P[\max_{1 \leq i \leq k-t} Z_i < \min_{k-t < j \leq k} Z_j + \sqrt{\Delta_t}] = P^t
\]

where \( Z_i \) (\( 1 \leq i \leq k \)) are independent standard normal random variables. [For the case \( t = 1 \), Dudewicz (1969) also obtained the result of Lemma 4.3 in a different form.]
Counterexample 4.4: Under the same setup as in Lemma 4.2,

\[ \lim_{n \to \infty} P(CS|P_Y, \hat{\delta}_1(t,n)) < P^* = \lim_{n \to \infty} P(CS|P_Y, \hat{\delta}_0(t,n)). \]

Proof

Note that \( 0 \leq \rho < 1 \), since \( \rho = \text{corr}(H_0, 2F-1) \) and \( H_0 \) and \( 2F-1 \) are monotone increasing in \( x \) for fixed \( \theta_0 \). Choose \( P^* \) and \( k \) large enough such that \( \Delta_t / \phi^{-1}(P^*)(k+1)/k < 1/\rho \). Substituting this into (4.1), the inequality follows. The equality is due to Theorem 2.7. \( \blacksquare \)

Through Counterexamples 4.1 and 4.4, we have seen that the SPC minimizes \( P(CS|P_Y) \) neither when one has a fixed sample size nor when one lets \( \delta^* = \theta_{[k-t+1]} - \theta_{[k-t]} \) tend to zero as \( n \to \infty \). Note that the logistic df possesses a monotone likelihood ratio with respect to its location parameter and has a support independent of its location parameter; thus imposing additional conditions such as the above two will not obviate the difficulty in the LFC.

It is an open question whether (for selection of the \( t \) best by \( P_Y \))

\[ \inf_{\omega_0(\delta^*, t)} P(CS|P_Y) = P(CS|P_Y, \hat{\delta}_0(t)). \]

5. Remarks on Selection Procedures based on Ranks.

In the literature of selection procedures based on ranks (either joint ranks or vector ranks) each contribution either imposes artificial restrictions on the parameter space (Puri
and Puri (1968), (1969), Gupta and McDonald (1970), and McDonald (1972), (1973), or is not able to find the LFC (Blumental and Patterson (1969)), or was partially invalidated by Rizvi and Woodworth (1970) (Lehmann (1963), and Bartlett and Govindarajulu (1968)). A conjecture as to why these procedures were invalidated is that the LFC's for them were sought in a parameter space where the P[CS] for certain parametric procedures is monotone while the P[CL] for rank procedures is not monotone (as is indicated by Gupta and McDonald (1970) and Blumental and Patterson (1969)).

For any procedures based on joint ranks or vector ranks, PRANK, define

$$R_{ID} = \frac{\inf_{\Omega_0(\hat{\theta}_0(t))} P[CS|P_{RANK}] - P[CS|P_{RANK},\hat{\theta}_0(t)]}{P[CS|P_{RANK},\hat{\theta}_0(t)]} \times 100$$

for the indifference zone approach, and

$$R_{SS} = \frac{\inf_{\Omega_0} P[CS|P_{RANK}] - P[CS|P_{RANK},EPC]}{P[CS|P_{RANK},EPC]} \times 100$$

for the subset-selection approach. Then the quantities $R_{ID}$ and $R_{SS}$ merit study because small $R_{ID}$ and $R_{SS}$ may well justify the SPC assumption (which will simplify theoretical development) while large $R_{ID}$ and $R_{SS}$ imply that the SPC assumption may be of only theoretical interest. [This aspect was called to our attention by Dr. Gary C. McDonald.]
We have noted in Section 4 that \( P_V \) also suffers in the LFC unless the SPC is assumed. Hence we wish to compute \( R_{ID} \) in the case of Counterexample 4.1 (where \( n = 2, \ k = 3, \) and the LFC is relatively simple). Our results on \( R_{ID} \) for \( p = .01(.01).99 \) (and some typical values of \( P[CS|P_V,SPC] \)) are summarized in Table 5.1. The minimum of \( P[CS|P_V,SPC] \) is .66146 (occurring at \( p = .50 \)) and the maximum \( R_{ID} \) is 3.11234% (occurring at \( p = .77 \)) out of the cases studied. These computations indicate that the assumption of the SPC as an underlying configuration may not be unreasonable. We propose that further study of \( R_{ID} \) and \( R_{SS} \) be carried out to see in how far this result generalizes to other cases.

**Table 5.1** \( R_{ID} \)

| \( p \) | \( P[CS|P_V,SPC] \) | \( R_{ID} \) (%) |
|-------|----------------|---------------|
| .01   | .98991         | .00327        |
| .10   | .89555         | .27168        |
| .20   | .79887         | .86522        |
| .30   | .72492         | 1.49768       |
| .40   | .67910         | 1.99793       |
| .50   | .66146 (minimum) | 2.36220     |
| .60   | .67014         | 2.69315       |
| .70   | .70420         | 3.01292       |
| .77   | .74403         | 3.11234 (maximum) |
| .80   | .76559         | 3.07632       |
| .90   | .86051         | 2.31874       |
| .99   | .98363         | .32231        |
6. Discussions

We have studied mathematical properties of the vector rank procedure when applied to selecting the largest location parameter in randomized block models. Even if the data is not quantitative but ordinal, or is not from a location model but from a stochastically ordered family of distributions, the vector rank procedure is applicable.

An important competing selection procedure is based on the robust estimate of location parameters (Sen and Puri (1972)). The selection procedure based on robust location estimates does not have the LFC difficulty that the vector rank procedure suffers from, and its relative efficiency compared to the means procedure is that of the Mann-Whitney-Wilcoxon test versus the t-test. A serious disadvantage, however, is that the robust location estimate method is not applicable if the data is ordinal or from a non-location family: for example, see Lee and Dudewicz (1980) where the data is incomplete rank order scores or Lee (1980) where the distributional origin of the data is not known.

We now discuss how to choose a proper selection procedure to be applied. If the data is from a location family, then the robust procedure of choice should be based on robust location estimates. If the data originates from a location family but in the ordinal form, or from a stochastically increasing scale parameter family, then the vector rank procedure may be applied to selecting the population with the largest parameter of interest. In this latter case, it is possible that the $P(\text{CS}) > P^*$ requirement is not met. In doubtful cases, the multinomial category selection procedure (Lee, 1980) is a possible alternative.
As a final remark, note that the procedure considered here is, like most robust selection procedures, not nonparametric since the required sample size (say (2.12) or (2.17)) depends on the underlying distribution, but is less sensitive to departure from the assumed underlying distribution than the means procedure.
