ABSTRACT

The present paper considers the stochastic difference equation $Y_n = M_n Y_{n-1} + Q_n$
where $M_n$ and $Q_n$ are respectively random $d \times d$ matrices and random $d$-vectors, and obtains some reasonable sufficient conditions on $M_n$ and $Q_n$ under which $Y_n$ converges in distribution. In addition, a particular model is examined when $d = 2$, in which the asymptotic independence of $Y_{1,n}$ and $Y_{2,n}$ results in a characterization of the Gamma distribution.
1. INTRODUCTION

In this paper we study the limit distribution of the solution $Y_n$ of the difference equation

\[(1.1) \quad Y_n = M_n Y_{n-1} + Q_n, \quad n \geq 1,\]

where $M_n$ are random $d \times d$ matrices, and $Q_n$ and $Y_n$ are $d$-vectors (where $d$ could be considered infinite, unless otherwise stated). Throughout we take the sequence of pairs $(M_n, Q_n)$, $n \geq 1$, to be independent and identically distributed. Equation (1.1) first came to our attention in a paper by Bernard, Shenton, and Uppuluri [1], in which it was used as a model for the distribution of radioactive material in the bone structure of humans. Since then, we have seen it arise in a variety of other contexts (see Soloman [9], and Cavalli-Sforza and Feldman [2], for examples).

The asymptotic behavior of (1.1) is examined in [10] by Vervaat in the special case where $d = 1$. A variety of conditions are given for the convergence in distribution of (1.1). In [5], Kesten establishes a reasonably general condition under which (1.1) converges for the cases where $d > 1$. In [5], it is shown that if

\[(1.2) \quad E(\ln ||M||)^+ < \infty\]

then there is a constant $\alpha$ where

\[(1.3) \quad \alpha = \lim_{n \to \infty} \frac{1}{n} \left| \left| M, \ldots, M_n \right| \right| \text{ a.s.},\]

where for a $d \times d$ matrix $M$ and a $d$-vector $x$, we define

\[(1.4) \quad \left| \left| M \right| \right| = \max_{\|x\| = 1} |Mx|, \text{ and }\]

\[(1.5) \quad |x| = \left( \sum_{i=1}^{d} x_i^2 \right)^{1/2}.\]

We then have in [5] that if
\[ (1.6) \]
\[
\begin{cases}
1) \alpha < 0 \text{ in } (1.3), \\
2) \text{there exists a } \beta > 0 \text{ where } E[Q_1]^\beta < \infty,
\end{cases}
\]

then (1.1) converges in distribution.

The first objective of this paper is to establish criteria other than (1.6) for the convergence of (1.1). While the conditions established will show that (1.6ii) can be weakened, that is not the aim of this paper. Instead, the criteria attempt to bypass what we perceive to be the major difficulty for applicability of [5], that is, the extreme difficulty in the determination of \( \alpha \) in (1.3).

In [7] and [10], the respective authors investigate possible limiting distributions of (1.1) in the case when \( d = 1 \), and achieve some partial results in classifying the limiting distributions. The second objective of this paper is to examine what criteria on the model (1.1) for \( d > 1 \) will yield a limit behavior in which the various components of the vector \( Y_n \) are asymptotically independent for a special model in which only a one-way reapportioning of material is allowed. We find that in most cases that non-trivial asymptotic independence is in general achieved only if the limit distribution of the components is a gamma distribution. As such, we arrive at a slight generalization of (Lukacs [6]).

2. CONVERGENCE OF THE DIFFERENCE EQUATION.

From (1.1), it is easy to see by iteration that

\[ (2.1) \]
\[ Y_n = \sum_{i=1}^{n} M_n \cdots M_{i+1}Q_i + M_n \cdots M_1 Y_0, \]

which, for given \( Y_0 \) has the same distribution as

\[ (2.2) \]
\[ R_n = \sum_{i=1}^{n} M_1 \cdots M_{i-1}Q_i + M_1 \cdots M_n Y_0. \]
We shall establish that in the case when $M_1 \ldots M_n \rightarrow 0$ a.s. exponentially fast, under weak conditions on $Y_0$ and $Q_n$, (2.2) will converge almost surely, independent of the distribution of $Y_0$. Then a variety of conditions which should be reasonably easy to check in particular cases will be given which are sufficient to guarantee that $M_1 \ldots M_n$ converge to zero exponentially fast.

For convenience, for any matrix $M$ and vector $Y$, we will use the typical notation

$$ (m_{ij}) = M, \quad (y_i) = Y. $$

Also, let us use the following notation, given matrices $M_1, \ldots, M_n$, and vector $x$;

$$ M^{(n)} = M_1 \ldots M_n, $$

$$ |x|_{\infty} = \sum_{i=1}^{d} |x_i|, $$

$$ |M|_{\infty} = \sup_{|x|_{\infty} = 1} |Nx|_{\infty}. $$

We now establish the main theorem in this section, which describes sufficient conditions for the almost sure convergence of (2.2).

**Theorem 2.1:** If there is a $0 < \lambda < 1$ where either i) $\lambda^{-n} \sup_{1 \leq j \leq d} \sum_{i=1}^{d} |m_{i,j}^{(n)}| \rightarrow 0$, a.s., $E(\ln|Q_1|_{\infty}) < \infty$, and $|Y_0|_{\infty} = \infty$, a.s., or ii) $\lambda^{-n} \sup_{1 \leq i \leq d} \sum_{j=1}^{d} |m_{i,j}^{(n)}| \rightarrow 0$, a.s., $E(\ln(\sup_{1 \leq i \leq d} |y_{0,i}|)) < \infty$, and $\sup_{1 \leq i \leq d} |y_{0,i}| = \infty$, a.s., then $R_n$ converges almost surely.

**Proof:** The proofs that condition i) and condition ii) are sufficient for the almost sure convergence of $R_n$ are similar, and as such, it will only be established for condition i).
We will establish that \( R_n \) is a Cauchy sequence with respect to the infinity norm, almost surely. That is, that for all \( \epsilon > 0 \), there is an \( N \) where

\[
(2.7) \quad P( |R_n - R_m|_\infty < \epsilon, \forall m, n > N ) > 1 - \epsilon.
\]

We will ignore the term \( M \), since it is clearly negligible. Then assuming \( n > m \),

\[
(2.8) \quad |R_n - R_m|_\infty = \sum_{i=1}^{d} |r_{n,i} - r_{m,i}|
\]

\[
\leq \sum_{j=m+1}^{n} \sum_{i=1}^{d} \sum_{k=1}^{d} |m_{i,k}^{(j-1)}||q_{j,k}|
\]

\[
= \sum_{j=m+1}^{n} \sum_{k=1}^{d} \sum_{i=1}^{d} |m_{i,k}^{(j-1)}||q_{j,k}|.
\]

Let

\[
(2.9) \quad C_n = \{ \omega: \sup_{n=N}^{\infty} \sup_{1 \leq i \leq d} |m_{i,k}^{(n)}| < \epsilon \},
\]

we have from (2.8) that

\[
(2.10) \quad |R_n - R_m|_\infty \leq I_{C_n}(\omega) \sum_{j=m+1}^{n} \sum_{k=1}^{d} \epsilon \lambda^{j-1}|q_{j,k}|
\]

\[
+ I_{\overline{C_n}}(\omega) \sum_{i=1}^{d} \sum_{k=1}^{d} \sum_{j=m+1}^{\infty} \sum_{k=1}^{d} |m_{i,k}^{(j-1)}||q_{j,k}|,
\]

where \( I_A(\omega) \) is the indicator function of a set \( A \).

Thus, from (2.10), we have that

\[
(2.11) \quad P( |R_n - R_m|_\infty > \epsilon, \text{some } n, m > N )
\]

\[
\leq P(\overline{C_n}) + P( \sum_{j=N+1}^{\infty} \sum_{k=1}^{d} \epsilon \lambda^{j-1}|q_{j,k}| > \epsilon )
\]

\[
= P(\overline{C_n}) + P( \sum_{j=N+1}^{\infty} \epsilon \lambda^{j-1}|Q_j| > \epsilon ).
\]
By lemma 2.2, to be presented later, we have that \( \sum_{i=1}^{\infty} \lambda^{i-1} |Q_i|_{\infty} \) converges almost surely if and only if \( E(\ln |Q_1|_{\infty})^+ < \infty \). From condition i) we have that there exists a \( \lambda, 0 < \lambda < 1 \), such that we have that for sufficiently large \( N \), \( P(C_n) > 1 - \varepsilon/2 \) for all \( n > N \). Thus, it is easy to see from (2.11) that for sufficiently large \( N \),

\[
P(|R_n^\infty - R_n^\infty| > \varepsilon, \text{ some } n, m > N) < \varepsilon/2 + \varepsilon/2 = \varepsilon,
\]

which establishes the theorem.

In [10], Verwaat establishes the lemma cited above (which is actually more general than the current requirements), which we now state for the sake of completeness.

**Lemma 2.2:** For \( \{X_i\}, \{Y_i\}, \) i.i.d. random variables, where \( -\infty < E(\ln |X_1|) < 0 \), then

\[
\sum_{i=1}^{\infty} (\prod_{j=1}^{i-1} X_j) Y_i \text{ converges a.s. if and only if } E(\ln |Y_1|) < \infty.
\]

We will now establish several criteria which are sufficient for the exponentially fast convergence of \( M_1 M_2 \ldots M_n \). To do this, we will appeal to a general lemma about functions on the matrices.

**Lemma 2.3:** If \( \{A_n\} \) is a sequence of i.i.d. random matrices, and \( f \) is some function such that \( f(A_{i+1} A_i) \leq f(A_i) f(A_{i+1}) \) and \( E(\ln f(A_1)) < 0 \), then there is a \( \lambda, 0 < \lambda < 1 \) where

\[
P(f(\prod_{i=1}^{n} A_i) > \lambda^n \text{ i.o.}) = 0.
\]

**Proof:** By assumption, we have that

\[
(2.13) \quad \ln f(\prod_{i=1}^{n} A_i) \leq \ln(\prod_{i=1}^{n} f(A_i)) = \sum_{i=1}^{n} \ln f(A_i).
\]

Thus, if we define \( \delta = -E \ln f(A_1) \), we have for any \( \gamma \) where \( 0 < \gamma < \delta \) that

\[
(2.14) \quad P(\sum_{i=1}^{n} \ln f(A_i) > -\gamma n \text{ i.o.}) = 0.
\]

As such, from (2.13) we have that
We get that for all $\lambda > e^{-\delta}$ the assertion is true.

Now we establish the first sufficient criteria for the convergence of $R_n$ which should be reasonably easy to verify in certain cases.

**Theorem 2.4.** If $E \ln (|Q_1(\omega)|^*) < \infty$, and $|Y_0(\omega)| < \infty$ a.s., then $R_n$ converges almost surely.

**Proof.** By condition i) of Theorem 2.1, we need only establish that

$$\lambda^{-n} \sup_{1 \leq j \leq d} \left( \sum_{i=1}^{d} |m_i(j)| \right) < 1, \text{ a.s.}$$

This follows quickly from Lemma 2.2 by noting that for all $x$ where $|Bx|_{\omega} = 0$,

$$|ABx|_{\omega} = \frac{|ABx|_{\omega}}{|Bx|_{\omega}} |Bx|_{\omega} \leq |A|_{\omega} |Bx|_{\omega},$$

where the inequality follows from the definition of theorem (2.6). Thus we have that $||AB||_{\omega} \leq ||A||_{\omega} ||B||_{\omega}$. As such, from the assumptions and lemma 2.2 we have that

$$P(\prod_{i=1}^{n} |M_i| > \lambda^n \text{ i.o.}) = 0.$$ 

This yields that for $\lambda < \lambda_1 < 1$, we have that

$$\lambda_1^{-n} ||\prod_{i=1}^{n} |M_i| ||_{\omega} = 0, \text{ a.s.}$$

As can be easily established from (2.6), we have that

$$||\prod_{i=1}^{n} |M_i| ||_{\omega} = \sup \left( \sum_{i=1}^{d} |m_i(n)| \right),$$

and the theorem is completed.
While the condition \( E \ln ||M_1||_\infty < 0 \) is not as formidable a condition to check as at first it appears, since formula (2.19) gives some hope of verifying \( E \ln ||M_1||_\infty < 0 \), nonetheless it is perhaps too difficult for certain models. The following theorem gives a simpler condition to check.

Using the matrix notation \( E[M] = (E|m_{i,j}|) \), we have the following theorem.

**THEOREM 2.5:** If \( d < \lambda , ||E[M_1]||_\infty < 1, E \ln(|Q_1|_\infty)^* < \infty \), and \( |Y_0|_\infty < \infty \), a.s., then \( R_n \) converges almost surely.

**PROOF:** Once again, by condition i) of theorem 2.1, we need only establish that for \( 0 < \lambda < 1, \lambda^{-n} \sup_{1 \leq j \leq d} |m_{i,j}| \rightarrow 0 \), a.s. Since \( ||E[M(1)]||_\infty < 1 \), we can choose a \( \lambda \) and \( \lambda_1 \) where \( ||E[M(1)]||_\infty < \lambda_1 < \lambda < 1 \). From (2.16), we have that

\[
(2.20) \quad \left| \sum_{k=1}^{n} E[M_k] \right|_\infty \leq \sum_{k=1}^{n} ||E[M_k]||_\infty < \lambda_1^n.
\]

Also, we have from the independence of the matrices

\[
(2.21) \quad E|m_{i,j}(2)| = E \sum_{k=1}^{d} m_{i,k} m_{k,j} \leq \sum_{k=1}^{d} E|m_{i,k}| E|m_{k,j}|,
\]

which along with (2.19) and (2.20) yields

\[
(2.22) \quad ||E[M_1 \ldots M_n]||_\infty \leq \left| \sum_{k=1}^{n} E[M_k] \right|_\infty < \lambda_1^n.
\]

Also, we have for \( \lambda > \lambda_1 \) that

\[
(2.23) \quad P(\sup_{n=m+1}^{\infty} |m_{i,j}(n)|) \leq \sum_{n=m+1}^{\infty} P(\sup_{1 \leq j \leq d} |m_{i,j}(n)| > \epsilon).
\]

Since

\[
\sum_{n=m+1}^{\infty} \lambda^{-n} \epsilon^{-1} E \sup_{1 \leq j \leq d} |m_{i,j}(n)|.
\]
we get from (2.23) that

(2.25) \[ \sum_{n=m+1}^{\infty} \lambda^{-n} \sup_{1 \leq j \leq d} \left( \sum_{i=1}^{d} |m_{i,j}^{(n)}| \right) > \varepsilon \leq \sum_{n=m+1}^{\infty} \lambda^{-1} \varepsilon^{-1} d \|E[M_1 \ldots M_n]\|_{\infty} \]

where the second inequality follows from (2.22).

As such, for a sufficiently large, we have

(2.26) \[ \sum_{n=m+1}^{\infty} \lambda^{-n} \sup_{1 \leq j \leq d} \left( \sum_{i=1}^{d} |m_{i,j}^{(n)}| \right) > \varepsilon \]

which completes the proof.

We now introduce another functional on matrices which is very similar to the spectral radius, first introduced by Dobrushin [33 in the case of stochastic matrices. For any \( d \times d \) matrix \( P = (p_{ij}) \), let us define an auxiliary matrix \( \hat{P} = (\hat{p}_{ij}) \) by

(2.27) \[
\hat{p}_{ij} = \begin{cases} 
1 & \text{if } i=1, j=1 \\
0 & \text{if } i>1, j=1 \\
1-\frac{d}{i} & \text{if } i=1, j>1 \\
\frac{d}{i-1} \hat{p}_{i-1,j-1} & \text{if } i>1, j>1 
\end{cases}
\]

Then we define our functional \( \delta(P) \) by

(2.28) \[
\delta(P) = \sup_{1 \leq i, k \leq d+1} \left( \sum_{j=1}^{d+1} |\hat{p}_{ij}^{(n)} - \hat{p}_{jk}^{(n)}| \right).
\]

**Lemma 2.6**: For any \( d \times d \) matrices \( P, Q \), where

\[
\sup_{1 \leq j \leq d} \left( \sum_{i=1}^{d} |p_{ij}| \right) = \sup_{1 \leq j \leq d} \left( \sum_{i=1}^{d} |q_{ij}| \right) = \infty, \quad \delta(PQ) < \delta(P) \delta(Q).
\]
PROOF: The functional $\delta$ is very similar to that of Dobrushin [3]. An examination of the proof that for stochastic matrices $P', Q'$, we have $\delta(P'Q') \leq \delta(P')\delta(Q')$, (see, Isaacson and Madsen [4]), yields that the crucial properties are

\begin{align*}
1) & \sum_{j=1}^{d+1} p_{ji} = 1, \quad \text{for all } i \\
2) & \sum_{k \in E} \sum_{j=1}^{d+1} p_{kj} (\hat{q}_{ji} - \hat{q}_{jk}) = \sum_{k \in E} \sum_{j=1}^{d+1} \hat{p}_{kj} (\hat{q}_{ji} - \hat{q}_{jk}) \quad \text{all } i, k.
\end{align*}

Since both are satisfied by the definition of $P$, $Q$, the proof is complete.

It should be noted that $\delta(\cdot)$ and $||\cdot||_\infty$ are very similar. In fact, if $P$ is a non-negative matrix, then it is easy to show that $\delta(P) = ||P||_\infty$. However, if $P$ is allowed to have negative values, it is possible that $\delta(P) < ||P||_\infty$ or $||P||_\infty < \delta(P)$. Because of this similarity in behavior, it is easy to see that a theorem similar to theorem 2.4 can be established for $\delta(M_{ij})$ by methods identical to those used in theorem 2.4, (we need only notice that from (2.2) we have $\delta(P) \geq \sup_{1 \leq i \leq d} \left( \sum_{j=1}^{d} p_{ij}^+ \right)$, $\delta(P) \geq \sup_{1 \leq i \leq d} \left( \sum_{j=1}^{d} p_{ij}^- \right)$, which yields that $2\delta(P) \geq \sup_{1 \leq i \leq d} \left( \sum_{j=1}^{d} |p_{ij}| \right)$. As such, we state without proof the following theorem.

**Theorem 2.7.** If $E \ln \delta(M_{ij}) < 0$, $E \ln (|q_{ij}|^+ < \infty$, and $|y_0|^\infty < \infty$ a.s., then $R_n$ converges almost surely.

It should be noted that theorems 2.4, 2.5, and 2.7 were applications of condition i) of theorem 2.1. It can be easily seen that by considering $M_1'$, the transpose of $M_1$, that theorems similar to 2.4, 2.5 and 2.7 can be established using condition ii) and virtually identical proofs to the theorems already established instead. However, both the statements and proofs of these theorems will be omitted in this paper.
3. LIMITING INDEPENDENCE FOR A PARTICULAR RANDOM DIFFERENCE MODEL.

In [7] and [10], the respective authors investigate possible limiting distributions of (1.1) for the case of $d=1$, and achieve some partial results in classifying possible limiting distributions. For $d=2$, we will examine for a special model the conditions under which the two components are asymptotically independent.

The model to be considered is the difference equation

$$\begin{align*}
\begin{bmatrix}
Y_{1,n} \\
Y_{2,n}
\end{bmatrix} &= \begin{bmatrix}
V_n & 0 \\
1-V_n & W_n
\end{bmatrix}
\begin{bmatrix}
Y_{1,n-1} \\
Y_{2,n-1}
\end{bmatrix} + \begin{bmatrix}
Q_n \\
0
\end{bmatrix},
\end{align*}$$

(3.1)

where $\{V_n, W_n, Q_n\}$ is an i.i.d. sequence, and $V_n, W_n, Q_n$ are independent of each other for all $n$. This represents a one-way flow storage model, in which at step $n$ new material is added to component one via $Q_n$, material is transferred from component one to component two via $1-V_n$, and material is lost from the system from component two via $1-W_n$.

For the model given in (3.1), if we let $Y_n \xrightarrow{d} Y$, and let

$$\begin{align*}
\phi(s,t) &= E(e^{isY_1 + itY_2}) \\
\psi(s) &= E(e^{isQ_1})
\end{align*}$$

(3.2)

then it is easy to verify from (3.1) that

$$\phi(s,t) = \psi(s)E\phi(sV_1 + t(1-V_1), tW_1).$$

(3.3)

Since $Y_1$ and $Y_2$ are independent if and only if $\phi(s,t) = \phi(s,0) \psi(0,t)$, we have from (3.3) that

$$\phi(s,t) = \phi(s) E\phi(sV_1 + t(1-V_1), 0) E\phi(0,tW_1).$$

(3.4)

Also from (3.3) it can also be shown that
(3.5) \[ \psi(s, t) = \psi(s) \Phi(t(1-V_1), tW_1) = \psi(s) \Phi(t(1-V_1), 0) \Phi(0, tW_1). \]

If we let

(3.6) \[ A = \{ s: \psi(s) = 0 \text{ or } \Phi(0, sW_1) = 0 \}, \]

and if \( A^c \) is dense, then by equating (3.4) and (3.5) one can see that for all \((s, t) \in A^c \times A^c\) that

(3.7) \[ \Phi(sV_1 + t(1-V_1), 0) = \Phi(sV_1, 0) \Phi(t(1-V_1), 0). \]

Then, by continuity of characteristic functions, we get that (3.7) holds for all \((s, t) \in \mathbb{R} \times \mathbb{R}\). Thus, under conditions sufficient to guarantee that \( A^c \) is dense, we get from (3.7) that \( Y_1, Y_2 \) are independent if and only if for \( V_1 \) independent of \( Y_1, V_1Y_1 \) and \((1-V_1)Y_1 \) are independent.

In the following, we will say

(3.8) \[ X \sim \Gamma(\lambda, \beta) \text{ if } P(X \leq x) = \begin{cases} 0 & \text{if } x \leq 0 \\ \frac{x}{\Gamma(\beta)^{-1}\lambda(\beta)^{-1}} e^{-\lambda y} dy & \text{if } x > 0, \end{cases} \]

and

(3.9) \[ X \sim B(\alpha, \beta) \text{ if } P(X \leq x) = \begin{cases} 0 & \text{if } x \leq 0 \text{ or } x \geq 1 \\ \int_0^x B(\alpha, \beta)^{-1} y^{\alpha-1}(1-y)^{\beta-1} dy & \text{if } 0 < x < 1. \end{cases} \]

The main result of the section is the following theorem.

**THEOREM 3.1:** For model (3.1), if \( V_1 \) and \( Y_1 \) are independent then \( V_1Y_1 \) and \((1-V_1)Y_1 \) are independent if and only if one of the following six conditions are true:
1) \( Y_1 = 0 \)
2) \( Y_1 = c, V_1 = d \)
3) \( V_1 = 0 \)
4) \( V_1 = 1 \)
5) \( Y_1 \sim \Gamma(\alpha, \beta), V_1 \sim B(a, \beta) \)
6) \(-Y_1 \sim \Gamma(\lambda, \alpha + \beta), V_1 \sim B(a, \beta) \)

To establish theorem 3.1, we will first establish the following lemma and intermediate theorem.

**Lemma 3.2:** Let \( U, W \) be independent random variables, where \( U > W > 0 \). Then \( U(U-W)^{-1} \) and \( U - W \) are independent if and only if \( U \equiv c, W \equiv d, c > d > 0 \).

**Proof:** It is clear there must be a constant \( e \) where

\[
(3.10) \quad P(U > e) = P(W \leq e) = 1
\]

If not, then we could find a \( b \) where \( P(U \leq b) > 0, P(W > b) > 0 \), but

\[
P(U \leq b, W > b) = 0, \text{ a contradiction.}
\]

Let

\[
(3.11) \quad \begin{cases} 
   b_2 = \inf \{b : P(W \leq b) = 1\}, \\
   b_3 = \sup \{b : P(U \geq b) = 1\}.
\end{cases}
\]

Then \( 0 < W \leq b_2 \leq b_3 \leq U \).

Since \( U - W \geq b_3 - b_2, W \leq b_2 \), we have that

\[
(3.12) \quad U(U - W)^{-1} \leq \frac{b_3}{b_3 - b_2}.
\]
Also, it is clear $P(U - W < b_3 - b_2 + \varepsilon) > 0$, for all $\varepsilon > 0$.

Since $U(U - W)^{-1}$, $U - W$ are independent, we have that

$$P(U(U - W)^{-1} > b_3(b_3 - b_2 + \varepsilon)^{-1}) = P(U(U - W)^{-1} > b_3(b_3 - b_2 + \varepsilon)^{-1} | U - W < b_3 - b_2 + \varepsilon).$$

And $U - W < b_3 - b_2 + \varepsilon$ implies

$$P(U(U - W)^{-1} > b_3(b_3 - b_2 + \varepsilon)^{-1}) = P(U(U - W)^{-1} > b_3(b_3 - b_2 + \varepsilon)^{-1} | U - W < b_3 - b_2 + \varepsilon).$$

As such, we have that $U - W < b_3 - b_2 + \varepsilon$ implies

$$P(U(U - W)^{-1} > b_3(b_3 - b_2 + \varepsilon)^{-1} | U - W < b_3 - b_2 + \varepsilon) = 1$$

for all $\varepsilon > 0$.

As such, from (3.13), we get

$$P(U(U - W)^{-1} > b_3(b_3 - b_2 + \varepsilon)^{-1} | U - W < b_3 - b_2 + \varepsilon) = 1$$

which in turn implies $U = b_3$, $V = b_2$.

Using this lemma, we can establish the next intermediate theorem.

**Theorem 3.3:** If $Y_1 \geq 0$, and if $V_1, Y_1$ are independent, then $V_1 Y_1$ and $(1 - V_1) Y_1$ are independent if and only if one of the five conditions below are true:

1) $Y_1 \equiv 0$,
2) $V_1 \equiv 0$,
3) $Y_1 \equiv 1$,
4) $Y_1 \equiv c$, $V_1 \equiv d$,
5) $Y_1 \sim \Gamma(\lambda, a+b)$, $V \sim \mathcal{B}(a, b)$. 

PROOF: The sufficiency is obvious, so we need only establish the necessity of the conditions. For convenience, let

(3.15) \( X = V_1 Y_1, \quad Z = (1-V_1)Y_1 \).

Further, let

\[
A_1 = \{Y_1 = 0\} = \{X = 0, \quad Z = 0\}
\]
\[
A_2 = \{Y_1 > 0, \quad V_1 < 0\} = \{X < 0, \quad Z > 0\}
\]
\[
A_3 = \{Y_1 > 0, \quad V_1 = 0\} = \{X = 0, \quad Z > 0\}
\]
\[
A_4 = \{Y_1 > 0, \quad 0 < V_1 < 1\} = \{X > 0, \quad Z > 0\}
\]
\[
A_5 = \{Y_1 > 0, \quad V_1 = 1\} = \{X > 0, \quad Z = 0\}
\]
\[
A_6 = \{Y_1 > 0, \quad V_1 > 1\} = \{X > 0, \quad Z < 0\}.
\]

Also, for the random variables \( V_1, Y_1, X, Z \), we define, respectively, the variable \( V_A, Y_A, X_A, Z_A \) for any arbitrary set \( A \) as the restriction of the variable to the set \( A \). That is, the distribution of variable \( V_A \) is given by

(3.17) \( P(V_A \leq x) = [P(V \subseteq A)]^{-1} P(V \leq x, V \subseteq A) \)

with the other variables defined identically.

As can be easily established, if \( V_1 \) and \( Y_1 \) are independent, than \( V_{A_1} \) and \( Y_{A_1} \) are also independent for all \( i \). Similarly, if \( X \) and \( Z \) are independent then so are \( X_{A_i} \) and \( Z_{A_i} \) for all \( i \).

To prove the theorem, we examine three cases,

1) \( P(Y_1 = 0) = 1 \)  \quad 2) \( P(Y_1 = 0) < 1, \quad P(0 < V_1 < 1) > 0 \) and 3) \( P(Y_1 = 0) < 1, \quad P(0 < V_1 < 1) = 0 \)

CASE I: \( P(Y_1 = 0) = 1 \).

In this case, we have nothing to prove, this being condition 1) of the theorem.
CASE II: \( P(Y_1=0) < 1, P(0<V_1<1) > 0. \)

In this case, \( P(A_2) = P(Y_1>0) \cdot P(0<V_1<1) > 0. \)

Clearly \( X_A > 0, Z_A > 0, \) and \( X_A \) and \( Z_A \) are independent. Also \( V_A, Y_A \) are independent, and as can be seen from (3.15), we have

\[
X_A + Z_A = Y_A, \quad X_A (X_A + Y_A)^{-1} = V_A.
\]

Thus from Lukacs characterization of the gamma distribution (see [6]), we have that

(3.18) \( X_A \sim \Gamma(\lambda, \alpha), Z_A \sim \Gamma(\lambda, \beta) \)

Also, we have that

(3.19) \( Y_A = X_A + Z_A \sim \Gamma(\lambda, \alpha+\beta) \).

Since \( Y_{(Y>0)} \sim Y_A \) for \( i = 1 \) (from the independence of \( Y_1 \) and \( V_1 \)), we have

for any \( i \neq 1 \) where \( P(A_i) > 0, \) that

(3.20) \( Y_A \sim Y_A \) for \( i \neq 1 \).

By similar arguments, we can also establish that for any \( i \) where \( P(A_i) > 0, \) we must have

\( X_1 \sim X_A \) for \( i > 4, \)

(3.21) \( Z_A \sim Z_A \) for \( 1 < i < 4 \).

Let us assume \( P(A_2) > 0. \) Then by letting

(3.22) \( U = Z_A, W = -X_A, \)

we have that \( U > W > 0. \) As can be easily established, \( U, W \) are independent, and \( W(U-W)^{-1} \), \( U-W \) are independent. Also, since \( W(U-W)^{-1} = U(U-W)^{-1} - I \), we can apply Lemma 3.2, yielding \( Z_A \sim c, X_A \sim -d. \) But since \( Z_A \sim \Gamma(\lambda, \beta) \), and from (3.21) we have \( Z_A \sim Z_A \), we have a contradiction which yields that \( P(A_2) = 0. \)

If \( P(A_0) > 0, \) we can generate by similar methods a contradiction for the distribution of \( X_0, \) so \( P(A_0) = 0. \) If \( P(A_3) > 0, \) we have \( X_A = 0, \) so \( Y_A = Z_A. \)
But from (3.20) and (3.21), we have $Y_A \sim \Gamma(\lambda, \beta)$ and $Z_A \sim \Gamma(\lambda, \alpha+\beta)$ yielding by contradiction that $P(A_3) = 0$. Similarly, we can show that $P(A_3) = 0$, yielding that $P(0 < V_1 < 1) = 1$. Thus we have that, letting $p_1 = P(Y_1 = 0)$, that

$$P(X \leq x, Z \leq z) = p_1 I(X=0, Z=0) + (1-p_1) \Gamma(\lambda, \alpha)(x) \Gamma(\lambda, \beta)(z)$$

Since $P(X=0)=P(Z=0) = P(X=0, Z=0) = p_1$, from independence of $X$ and $Z$, we have that $p_1 = p_1^2$ which yields that $p_1 = 0$ since $p_1 < 1$. This yields condition 5) of the theorem.

CASE III: $P(Y_1 = 0) < 1$, $P(0 < V_1 < 1) = 0$.

Since $P(Q < V_1 < 1) = 0$, we have $P(X>0, Z>0) = 0$. Thus, either $P(X>0) = 0$, or $P(Z>0) = 0$. Assume $P(Z>0) = 0$. Then $P(V_1 < 0) = 1$. In addition, assume that $P(V_1 < 0) > 0$, so we have $P(A_2) > 0$, and by applying Lemma 3.2 to $X_{A_2}, Z_{A_2}$, we get $Z_{A_2} = c, X_{A_2} = -d, c>d>0$. Thus $Y_{A_2} = Z_{A_2} + X_{A_2} = c - d > 0$. If $P(V_1 = 0) > 0$ also, we have $P(A_3) > 0$. By (3.20) and (3.21), we get that $Y_{A_3} \sim Y_{A_2} = c - d$, and $Z_{A_3} \sim Z_{A_2} = c$. But we must have $Z_{A_3} = Y_{A_3}$ which gives a contradiction. Thus, if $P(V_1 < 0) > 0$, then $P(V_1 = 0) = 0$ which yields that $P(V_1 < 0) = 1$.

Thus, we have for $P(Y_1 = 0) = p_1$

$$P(X=0, Z=0) = p_1$$
$$P(X=-d, Z=-c) = (1-p_1)$$

which clearly contradicts the independence of $X$ and $Z$ unless $p_1 = 0$ or $p_1 = 1$.

Thus we have $X$ and $Z$ are degenerate, which yields condition 4). If we assume instead that $P(V_1 = 0) > 0$ in addition to $P(Z>0) = 0$, a contradiction similar to the one above will show that $P(V_1 = 0) = 1$, which is condition 2).
If we assume that \( P(X>0) = 0 \), arguments identical to those above will show that \( P(V_1=1) = 0 \) or \( P(V_1>1) = 1 \), which yield, respectively, condition 4) or condition 5).

We are now ready to establish the main theorem of this section.

**Theorem 3.4.** If \( V_1, Y_1 \) are not both degenerate, then \( V_1, Y_1 \) independent and \( V_1Y_1 \) and \( (1-V_1)Y_1 \) are independent if and only if one of the five conditions below are true:

1) \( Y_1 \equiv 0 \),
2) \( V_1 \equiv 0 \),
3) \( V_1 \equiv 1 \),
4) \( Y_1 \sim \Gamma(\lambda, \alpha+\beta), \ V_1 \sim \beta(\alpha, \beta) \)
5) \( -Y_1 \sim \Gamma(\lambda, \alpha+\beta), \ V_1 \sim \beta(\alpha, \beta) \).

**Proof:** Again the sufficiency is obvious, so we need only establish the necessity of the conditions. If we have either \( P(Y_1>0) = 1 \), or \( P(Y_1<0) = 1 \), then by theorem 3.3 we have that one of the 5 conditions must hold (where the new condition, condition 5) follow when \( P(Y_1<0) = 1 \). Thus from now on we will assume \( P(Y_1<0) > 0, \ P(Y_1>0) > 0 \).

In addition to the sets \( A_1 \) to \( A_6 \) defined in theorem 3.3, we define the sets

\[
\begin{align*}
A_7 &= \left\{ Y_1<0, V_1<0 \right\} = \{X>0, Z<0, X+Z<0\} \\
A_8 &= \left\{ Y_1<0, V_1=0 \right\} = \{X=0, Z<0\} \\
A_9 &= \left\{ Y_1<0, 0<V_1<1 \right\} = \{X<0, Z<0\} \\
A_{10} &= \left\{ Y_1<0, V_1=1 \right\} = \{X<0, Z=0\} \\
A_{11} &= \left\{ Y_1<0, V_1>1 \right\} = \{X<0, Z>0, X+Z<0\},
\end{align*}
\]
and we redefine

\[
\begin{align*}
A_2 &= \{(x<0, z>0, x+z>0) \} \\
A_6 &= \{(x>0, z<0, x+z>0) \}
\end{align*}
\]  
(3.26)

Note that while for all i, \( A_i \) can be expressed as \( A_i = \{Y_i \in A, V_i \in B\} \) (for some borel sets A, B) the sets \( A_2, A_6, A_7, A_{11} \), cannot be expressed as sets of the form \( \{x \in A, z \in B\} \).

Let us assume in addition to \( P(Y_1 < 0) > 0, P(Y_1 > 0) > 0 \), that \( P(0 < V_1 < 1) > 0 \) (this assumption will be shown to yield a contradiction later).

Thus we have \( P(A_2) > 0, P(A_6) > 0 \). By appealing to Lukacs characterization as in Theorem 3.3, we get

\[
\begin{align*}
x_A \sim \Gamma(\lambda_1, \alpha_1), & \quad z_A \sim \Gamma(\lambda_1, \beta_1), & \quad y_A \sim \Gamma(\lambda_1, \alpha_1, \beta_1) \\
-x_A \sim \Gamma(\lambda_2, \alpha_2), & \quad -z_A \sim \Gamma(\lambda_2, \beta_2), & \quad -y_A \sim \Gamma(\lambda_1, \alpha_1, \beta_1).
\end{align*}
\]  
(3.27)

By arguments similar to those used for (3.20) and (3.21), we have that if

\[ P(A_6 \cup A_7) > 0, P(A_2 \cup A_{11}) > 0, \]

then

\[
\begin{align*}
x_{A_6 \cup A_7} \sim \Gamma(\lambda_1, \alpha_1), & \quad z_{A_6 \cup A_7} \sim \Gamma(\lambda_1, \beta_1) \\
-x_{A_2 \cup A_{11}} \sim \Gamma(\lambda_2, \alpha_2), & \quad -z_{A_2 \cup A_{11}} \sim \Gamma(\lambda_1, \beta_1).
\end{align*}
\]  
(3.28)

Since \( P(A_6 \cup A_7) > 0 \), assume that \( P(A_6) > 0 \). Thus we get for \( x_0 > 0, y_0 < 0 \) that

\[
P(x_{A_6} \leq x_0, z_{A_6} \leq z_0) = \int_{A_6} \frac{\alpha_1 \alpha_1^{-1} e^{-\lambda_1 x} \beta_2 \beta_2^{-1} \lambda_2 z}{\Gamma(\alpha_1) \Gamma(\beta_2) P(A_6)} \, dx \, dz
\]  
(3.29)

where \( A = \{(x,z) : x < x_0, z < z_0, x+z>0\} \).

Also, by arguments similar to those used for (3.20) and (3.21), we have that

\[
Y_{A_6} = x_{A_6} + z_{A_6} \sim \Gamma(\lambda_1, \alpha_1, \beta_1).
\]  
(3.29)
Thus, by transformation of variables in (3.28), we get that
\[
(3.30) \quad \frac{\beta_1^{\gamma_1} \alpha_1^{\beta_1-1}}{\lambda_1^{\gamma_1} \lambda_2^{\beta_2-1}} = \frac{\Gamma(\alpha_1+\beta_1)}{\Gamma(\alpha_1)\Gamma(\beta_1)P(A_0)} \int_0^{\infty} (y+w) e^{-y} w \, dw.
\]
By examining the behavior of the right hand side of (3.30) and the left hand side of (3.30) (particularly as \(y\) approaches 0), we get that equality is impossible for \(\alpha_1 > 0, \beta_1 > 0\). Thus, we have that \(P(A_0) = 0\). Similarly, we can establish that \(P(A_7) = 0\). Thus \(P(X > 0, Z < 0) = P(A_0 \cup A_7) = 0\). However, since we have assumed that \(P(Y_1 > 0) > 0, P(Y_1 < 0) > 0, \) and \(P(0 < V_1 < 1) > 0\), we get from the definition of \(X\) and \(Z\) (see (3.15)), that \(P(X > 0) > 0, P(Z < 0) > 0\). This yields a contradiction in the assumption \(P(0 < V_1 < 1) > 0\). Thus, we conclude that \(P(0 < V_1 < 1) = 0\), and we have that \(P(X > 0, Z > 0) = P(X < 0, Z < 0) = 0\).

From this, we can quickly deduce the rest of the criteria. Since \(P(Y_1 > 0) > 0, \) and \(P(Y_1 < 0) > 0, \) then the assumption that \(P(V_1 < 0)\) yields from (3.15) that \(P(X < 0) > 0, P(Z > 0) > 0\). Independence of \(X\) and \(Z\) yields that \(P(X < 0, Z < 0) > 0\), which is a contradiction. Thus, \(P(V_1 < 0) = 0\). In a similar manner, \(P(V_1 > 1) = 0\). Thus \(P(V_1 = 0) + P(V_1 = 1) = 1\). If \(P(V_1 = 0) > 0, P(V_1 = 1) > 0, \) we again can show from (3.15) that \(P(X > 0) > 0, P(Z > 0) > 0, \) which again contradicts \(P(X > 0, Z > 0) = 0\). Thus we have either \(P(V_1 = 0) = 0, P(V_1 = 1) = 1 \) (condition 3) or \(P(V_1 = 0) = 1, P(V_1 = 1) = 0 \) (condition 2).

To relate Theorem 3.4 to the asymptotic independence of \(Y_{1,n}\) and \(Y_{2,n}\), we only need to observe as remarked after (3.7) that for any condition sufficient to guarantee the density of \(A^C\) (see (3.6)), \(X_1\) and \(Y_2\) are independent if and only if for \(V_1, Y_1\) independent, \(V_1Y_1\) and \((1-V_1)Y_1\) are also independent. As such, for \(A^C\) dense, Theorem 3.4 gives the necessary and sufficient condition for asymptotic independence. The most reasonable and realistic condition on \(Q_n, V_n, W_n\) for Theorem 3.4 to be applicable are given in the following corollary.
COROLLARY 3.5 If $Q_n \geq 0$, $0 \leq V_n \leq 1$, $W_n \geq 0$ then $Y_{1,n}$ and $Y_{2,n}$ are asymptotically independent if and only if $Q_n$ has a Gamma distribution and $V_n$ has a Beta distribution, or one of the four trivial conditions of Theorem 3.3 are met by $Q_n$ and $V_n$.

The proof follows immediately from Theorem 3.4 and the fact that the characteristic functions of non-negative random variables have dense support (see Smith [8]).

Clearly, other restrictions to $Q_n$, $V_n$, and $W_n$ will yield that the only case of asymptotic independence of $Y_{1,n}$ and $Y_{2,n}$ are when $Q_n$ has a Gamma distribution and $V_n$ has a Beta distribution. However, the more interesting question of a characterization of the distributions of $Q_n$, $V_n$ and $W_n$ that result in $Y_{1,n}$ and $Y_{2,n}$ being asymptotically independent appears to be an open question.
REFERENCES

The present paper considers the stochastic difference equation \( Y_n = M_n Y_{n-1} + Q_n \)
where \( M_n \) and \( Q_n \) are respectively random \( d \times d \) matrices and random \( d \)-vectors, and obtains some reasonable sufficient conditions on \( M_n \) and \( Q_n \) under which \( Y_n \) converges in distribution. In addition, a particular model is examined when \( d = 2 \), in which the asymptotic independence of \( Y_{1,n} \) and \( Y_{2,n} \) results in a characterization of the Gamma distribution.
