"Infrared and Ultrasonic Spectra of Sodium Thiocyanate and Lithium Thiocyanate in Tetrahydrofuran"

D. Saar and S. Petrucci

"Infrared spectra of sodium thiocyanate solutions and of lithium thiocyanate solutions in tetrahydrofuran (THF) in the wavenumber range 2000-2200 cm\(^{-1}\) are reported. The digitized spectral envelope, which is due to the out of phase stretch of the SCN anion, is quantitatively described by the sum of three Gaussian-Lorentzian product functions. The three spectral bands are assigned respectively, to the N-bonded ion pairs (\(2057\) cm\(^{-1}\) for NaNCS, 2063 cm\(^{-1}\) for LiNCS), to the dimers or quadrupoles (\(2041\) cm\(^{-1}\) for NaNCS, 2057 cm\(^{-1}\) for LiNCS)."
(NaNCS)₂, 2040 cm⁻¹ for (LiNCS)₂, and tentatively to triple ions (2074 cm⁻¹ for sodium thiocyanate, 2086 cm⁻¹ for lithium thiocyanate). The maximum absorbances per unit length of cell are expressed as a function of concentrations by cubic polynomial functions.

Ultrasonic spectra for sodium thiocyanate solutions in THF in the frequency range 0.5-400 MHz are described by the sum of two Debye relaxation functions. The ultrasonic spectra for sodium thiocyanate in THF are interpreted as due to a two step process:

\[ 2\text{NaNCS} \rightleftharpoons \text{NaNCS}...\text{NaNCS} \rightleftharpoons (\text{NaNCS})₂ \]

depicting the two steps dimerization of the ion pair NaNCS, the intermediate being a solvent separated species. For lithium thiocyanate solutions in THF, the ultrasonic spectra are described by a single Debye relaxation function, and interpreted by the dimerization scheme 2LiNCS \rightleftharpoons LiNCS...LiNCS, the product of the reaction being mostly a solvent separated species, the "contact" species being probably in lesser amounts than for (NaNCS)₂ in accordance with the evidence from the infrared spectra.

The limitations of the infrared method in giving reliable formation stoichiometric constants in media of low permittivity are discussed. The advantage of combining the structural information from vibrational spectra to the kinetic results of the ultrasonic spectra for a molecular interpretation of the latter ones is reiterated.
Infrared and Ultrasonic Spectra of Sodium Thiocyanate and Lithium Thiocyanate in Tetrahydrofuran

Long Island Center, Farmingdale N.Y., 11735

Abstract

Infrared spectra of sodium thiocyanate solutions and of lithium thiocyanate solutions in tetrahydrofuran (THF) in the wavenumber range 2000–2200 cm\(^{-1}\) are reported. The digitized spectral envelope, which is due to the out of phase stretch of the SCN anion, is quantitatively described by the sum of three Gaussian-Lorentzian product functions. The three spectral bands are assigned respectively, to the N-bonded ion pairs (~2057 cm\(^{-1}\) for NaNCS, ~2064 cm\(^{-1}\) for LiNCS), to the dimers or quadrupoles (~2043 cm\(^{-1}\) for (NaNCS)\(_2\)), 2040 cm\(^{-1}\) for (LiNCS)\(_2\), and tentatively to triple ions (2074 cm\(^{-1}\) for sodium thiocyanate, ~2080 cm\(^{-1}\) for lithium thiocyanate). The maximum absorbances per unit length of cell are expressed as a function of concentrations by cubic polynomial functions.

Ultrasonic spectra for sodium thiocyanate solutions in THF in the frequency range 0.5-400 MHz are described by the sum of two Debye relaxation functions. The ultrasonic spectra for sodium thiocyanate in THF are interpreted as due to a two step process:

\[
2 \text{NaNCS} \rightarrow \text{NaNCS...NaNCS} \rightarrow (\text{NaNCS})_2
\]

depicting the two steps dimerization of the ion pair NaNCS, the intermediate

* Colgate-Palmolive Co., Piscataway, N.J.
being a solvent separated species. For lithium thiocyanate solutions in THF, the ultrasonic spectra are described by a single Debye relaxation function and interpreted by the dimerization scheme \(2\text{LINCS} \rightarrow \text{LINCS}_{\ldots} \text{LINCS}\), the product of the reaction being mostly a solvent separated species, the "contact" species being probably in lesser amounts than for \((\text{NaNCS})_2\) in accordance with the evidence from the infrared spectra.

The limitations of the infrared method in giving reliable formation stoichiometric constants in media of low permittivity are discussed. The advantage of combining the structural information from vibrational spectra to the kinetic results of the ultrasonic spectra for a molecular interpretation of the latter ones is reiterated.

Introduction

Recently there has been a renewed interest,\(^1\) after the classical work of Fuoss and Kraus\(^2\) of the thirties, in the association and dimerization of electrolytes in media of low permittivity. The practical relevance of these systems, especially lithium salts in ethereal solutions, is due to their use in the construction of secondary batteries. The knowledge of the state of association of the electrolyte and of the lifetime of the complex species is essential for the optimal choice of solvent and electrolyte. Despite recent advances in application of transport theories of electrolytes,\(^3\) theoretical new expressions for the formation constant of dimers ion-pairs\(^4\) and triplets,\(^5\) our knowledge of the structure of the complex species in solution is scarce or non-existing.

To this end a program by vibrational IR spectra combined to the already existing molecular relaxation dynamic methods (microwave dielectric relaxation and/or ultrasonic relaxation) has been initiated. For the present work the electrolytes sodium thiocyanante and lithium thiocyanate in the solvent THF have been examined. For the IR spectra the intramolecular vibration of the anion,
specifically the out of phase stretch of the SCN\(^-\) anion,\(^6\) (or, in the group frequency jargon the "CN stretch") and its changes due to molecular environments have been used as a probe to study the molecular complexation of the electrolytes.

Ultrasonic relaxation spectra of the same systems are also reported, using the structural information from the IR spectra, for their interpretation.

Experimental

The IR spectra have been recorded by a Perkin-Elmer 983G spectrometer, using scan times and slit program modes (4 and 16, respectively) slow enough that no spectral distortion was noticed with respect to slower modes. The cells were calibrated by the fringe method\(^7\) before each collected spectrum. They were demountable Perkin-Elmer cells with 0.05 mm teflon spacers. Both CaF\(_2\) and NaCl windows were used, ensuring independence of the spectra from the material of the windows, hence their inertness to possible dissolution into the liquid. The ultrasonic instrumentation, data collection and method have been described extensively in previous works.\(^8\). Sodium thiocyanate and lithium thiocyanate (Baker reagents with analysis certificate) were re-dried at \(-70^\circ C\) and \(110^\circ C\), respectively \textit{in vacuo} \((\sim 1mm)\), in volumetric flasks until constancy of weight. Solutions were prepared by volume addition of THF (Baker ACS) dried over molecular sieves (5A 0\(^0\)). The molecular sieves had been dried for many hours at \(\sim 140^\circ C\) and cooled \textit{in vacuo}. Infrared spectra of the THF product as received, showed a faint band at \(\sim 3300\) cm\(^{-1}\) which disappeared after a few days exposure to molecular sieves. This indicated absence of water in this product, within the resolution of the 983G spectrometer set with an ordinate scale of 0.25 in absorbance (\(A = 0.0025/\) minimum division).
Results and Calculations

Some of the infrared spectra expressed in absorbance vs. wavenumber (cm\(^{-1}\)) are depicted in Figs. 1 and 2. The spectra for sodium thiocyanate show rather dramatically the relative change of the two visible bands with total concentration of electrolyte.

For lithium thiocyanate the satellite band is the one at lower wavenumbers at variance with the case of sodium thiocyanate indicating qualitatively a different molecular distribution of the species present for the two electrolytes.

For the quantitative interpretation of the spectra they were digitized with a resolution of 2.5 cm\(^{-1}\) (1.25 cm\(^{-1}\) near the peaks and shoulders). It is known that Lorentzian functions are particular applicable to gases and Gaussian functions are particularly applicable to solids in terms of the band shape of vibrational spectra. For the present case the empirical Gaussian-Lorentzian product function already used before has been applied

\[
A_j = A_j^{o}(\exp\left[\frac{-(\nu-\bar{\nu}_j)^2}{2\sigma_j^2}\right])\left(1 + \frac{(\nu-\bar{\nu}_j)^2}{\sigma_j^2}\right)^{-1}
\]

with \(A_j^{o}\) the absorbance at the center band wavenumber \(\bar{\nu}_j\), \(\sigma_j\) the variance \(\sigma_j = \frac{(\Delta\nu)_{1/2}}{1.46}\), with \((\Delta\nu)_{1/2}\) the bandwidth at \((1/2)A_j^{o}\) for each band. For the spectra of the present work it has resulted to be necessary the use of three Gaussian-Lorentzian bands for a quantitative interpretation of the absorbance envelope, hence

\[
\Lambda = \sum_j A_j \quad (J = 1,2,3)
\]

The parameters used to interpret the spectra are collected in Table I for all the concentrations of sodium thiocyanate and of lithium thiocyanate investigated in THF. Figs 3 and 4 report representative plots of the digitized spectra for sodium thiocyanate and lithium thiocyanate in THF with the indicated band
components (dashed lines) and their sum (solid lines) describing the absorbance envelope.

Representative plots of the ultrasonic spectra for sodium thiocyanate and lithium thiocyanate in THF are reported in Fig. 5 and Fig. 6. For the case of sodium thiocyanate two Debye processes are necessary to interpret the spectra expressed as excess sound absorptions per wavelength \( \mu = (\alpha - \text{Im}^2)u/f \), vs the frequency \( f \). In the above, \( \alpha \) is the sound attenuation coefficient, \( B \) is the background sound absorption ratio \( \alpha/f^2 \) at \( f \gg f_1, f_2 \) with \( f_1 \) and \( f_2 \) the two relaxation frequencies, \( B = (\alpha/f^2)f \gg f_1, f_2 \), \( u \) is the sound velocity. Therefore:

\[
\mu = 2\mu_1 \frac{(f/f_1)}{1 + (f/f_1)^2} + 2\mu_2 \frac{(f/f_2)}{1 + (f/f_2)^2}
\]

where \( \mu_1 \) and \( \mu_2 \) are the maximum sound excess absorptions for the two Debye processes centered at \( f_1 \) and \( f_2 \), respectively.

Table II collects all the calculated relaxation parameters and the sound velocities \( u \) for the concentrations investigated for sodium thiocyanate and lithium thiocyanate in THF at 25°C.

Discussion

a) Vibrational spectra

The thiocyanate anion is known to be a potentially ambidentate ligand. It is a linear ion which may ligate through the nitrogen or sulfur atom. The three frequencies of the thiocyanate ion are the out-of-phase stretch \( \nu_1 \), with characteristic frequency at 2050 cm\(^{-1} \), the in phase stretch \( \nu_3 \) with characteristic frequency at 735 cm\(^{-1} \), and the bending (double degenerate) mode \( \nu_2 \) with frequency \( \nu_2 = 480 \text{cm}^{-1} \). These group frequencies (here used as a jargon in place of the more correct term wavenumber) change characteristically depending on the coordination mode. Specifically, N-bonded complexes cause an increase of
\(\nu_1, \nu_2\) does not change and \(\nu_3\) increases, whereas S-bonded complexes show a larger \(\nu_1\) increase but a decrease of both \(\nu_2\) and \(\nu_3\) both being more diagnostic than \(\nu_1\), in determining the bonding end of the anion. However solvent bands often obscure the \(\nu_2\) and \(\nu_3\) regions. Previous work\(^{10-12}\) has established that with "hard" poorly polarizable ions as \(\text{Na}^+\) and \(\text{Li}^+\) the ion pairs contact complexes are N-bonded with a respective increase of \(\sim 8\text{cm}^{-1}\) and \(\sim 15\text{cm}^{-1}\) of the center band frequency with respect to the spectroscopically free (ion and outer-sphere ion-paired) SCN\(^-\) anion.

On the basis of the above, one would attribute the band at \(\approx 2057\text{cm}^{-1}\) for NaNCS and \(\approx 2064\text{cm}^{-1}\) for LiNCS in THF (Table I) to contact ion pairs. No free ions or outer-sphere ion pairs are detectable. Past work in this laboratory\(^1\) and previous one by Chabanel et al\(^12\) have attributed the band at \(\sim 2040\) to contact dimer ion-pairs or quadrupoles (NaNCS)\(_2\) and (LiNCS)\(_2\).

One has to keep in mind however that the bands at 2057\text{cm}^{-1} and 2064\text{cm}^{-1}, respectively could also account for solvent separated dimers (NaNCS...NaNCS)\(_2\) and (LiNCS...LiNCS)\(_2\) which would be spectroscopically indistinguishable from the monomer species NaNCS and LiNCS.

Therefore, for instance for sodium thiocyanate solutions any calculation of formation constants based on relations as \(A_{2057}^0 = \epsilon_p c_p\) and \(A_{2040}^0 = \epsilon_q c_q\) is destined to fail if outer-sphere dimers are present. In the above \(\epsilon_p\) and \(\epsilon_q\) are the extinction coefficients of the ion-pair and quadrupole respectively, \(c_p\) and \(c_q\) the corresponding concentrations, \(l\) the length of the cell. In other words, even if retained, assumptions as \(2\epsilon_p = \epsilon_q\) are correct, the calculated \(K_q = c_q/c_p^2\) is going to be void of significance if outer-sphere dimers are present. This is because, in this case \(A_{2040}^0 = \epsilon_q c_q^\text{contact}\) and \(A_{2057}^0 = \epsilon_p(c_p + c_q^\text{outer-sphere})\). The calculated \(K_q = c_q^\text{contact}/(c_p + c_q^\text{outer-sphere})^2\) would then become strongly concentration dependent. Presence of solvent separated dimers is consistent with the results
of the ultrasonic analysis of the data given below.

The small bands at 2074 cm\(^{-1}\), respectively for sodium thiocyanate and lithium thiocyanate have a less definite interpretation than the ones for the other two bands which has also been confirmed by normal coordinate analysis\(^{12}\). We tentatively attribute these bands at 2074 cm\(^{-1}\) and 2080 cm\(^{-1}\) to triple ions existing at lower concentration than the other species. The latter is suggested by the smallness of the \(A^0\)'s.

Because of the above considerations, we think that it is safe not to over extend vibrational spectrometry beyond its present capability in trying to calculate formation constants at low permittivities where, because of electrostatic forces larger population of outersphere dimers may exist. The same warning referred to ion pairs, in solvent of intermediate permittivity, was given by some of us in a past work\(^{10}\). The method may by approximately correct for ion-pairs in aqueous solutions because of its large permittivity, although even in this case for metal (II) sulfates, large concentration of outer species ion pair appear to exist.\(^{14}\) Accordingly, we have only calculated the concentration dependence of the individual maximum absorbances per unit length of cells \(\phi\) by fitting the data to cubic polynomials as reported below.

For sodium thiocyanate in THF:

\[
A^{0}_{2043/0} = -0.31 + 603.1c + 2187.5c^2 - 8649c^3; r^2 = 0.998
\]

\[
A^{0}_{2057/0} = 0.1096 + 516.6c + 483c^2 - 4942c^3; r^2 = 0.998
\]

\[
A^{0}_{2074/0} = 0.0131 - 56.34c + 1195c^2 - 2334c^3; r^2 = 0.999
\]

For lithium thiocyanate solutions in THF

\[
(A^{0}_{2040/0}) = -0.0006 + 51.980c + 379.80c^2 - 285.95c^3; r^2 = 0.99999
\]
\[
(A_{2064/\beta}^0) = -0.252 + 1610.7c + 5395.9c^2 + 13,400c^3; \ r^2 = 0.9987
\]

\[
A_{2080/\alpha}^0 = 0.1170 - 17.180c^2 + 1254.4c^2 - 3320.8c^3; \ r^2 = 0.9925
\]

The above expressions have been calculated by non-linear regression giving 50\% statistical weight to the origin. It is noteworthy that the bands at 2043 cm\(^{-1}\) and 2061 cm\(^{-1}\) for sodium thiocyanate and lithium thiocyanate solutions may also be expressed as simple linear functions of c with an almost comparable determination coefficient \(r^2\) (dashed lines in Fig. 7) and Fig. 8.

For sodium thiocyanate in THF:

\[
A_{2043/\alpha}^0 = -0.34 + 714.2c; \ r^2 = 0.997
\]

For lithium thiocyanate in THF:

\[
A_{2064/\gamma}^0 = 3.08 + 111.1c; \ r^2 = 0.9948
\]

From the analysis of the IR-spectra it would appear therefore that contact dimers are the dominant species for sodium thiocyanate in THF with an almost comparable amount of "spectroscopically" free monomers (free ion-pairs and outersphere dimers). On the contrary for lithium thiocyanate in THF, the latter two species appear as the dominant species. This is in line with the relative solvation tendencies of Li\(^+\) vs. Na\(^+\) ions.

b) Ultrasonic Spectra

The ultrasonic spectra and the data collected in Table II for sodium thiocyanate in THF can now be interpreted on the basis of the structural information gathered through the IR-spectra. Simple concentration distribution calculations of the various species present in THF with reasonable formation constant parameters as \(K_p = 10^8 M^{-1}\), \(K_T = 10^6 M^{-1}\) and \(K_q = 10 M^{-1}\) (for the ion pair, triple and quadruple formation constants) reveal that in the concentration range 0.05 to 0.2M the ion pair and quadrupole concentrations are of the same
order of magnitude but that \( c_p, c_q \ll c_t \), the triple ion concentration.

It is therefore unlikely that the source of any of the two Debye relaxation processes be due to equilibria involving triple ions. Accordingly, we have interpreted the ultrasonic relaxation spectra for sodium thiocyanate in THF according to the two step dimerization equilibrium

\[
2 \text{AB} \xrightleftharpoons[k_1][k_-1] \text{AB} \cdots \text{AB} \xrightleftharpoons[k_2][k_-2] (\text{AB})_2
\]

where

\[
\text{AB} = \text{NaNCS}, \quad \text{AB} \cdots \text{AB} = \text{NaNCS} \cdots \text{NaNCS} \quad \text{and} \quad (\text{AB})_2 = (\text{NaNCS})_2
\]

The above leads to two relaxation times \( \tau_1 \) and \( \tau_\text{II} \), where

\[
\tau_\text{II}^{-1} = \frac{1}{2} [S \pm \sqrt{S^2 - 4P}]
\]

\[
S = \tau_1^{-1} + \tau_\text{II}^{-1} = 4k_1(\text{AB}) + k_1 + k_2 + k_-2
\]

\[
P = \tau_1^{-1}x\tau_\text{II}^{-1} = 4k_1(\text{AB})(k_2 + k_-2) + k_1k_-2
\]

and

\[
\tau_1^{-1} = 2\pi f_1\tau_\text{II}^{-1} = 2\pi f_\text{II}.
\]

Assuming as a first approximation \( AB \approx c \), the stoichiometric concentration, Fig. OA and Fig. OB have been constructed.

Linear regression of \( S \) vs \( c \) gives slope 1.37x10^9, Int = 3.55x10^8, \( r^2 = 0.96 \)

Linear regression of \( P \) vs \( c \) gives (Slope)' = 1.64x10^17 (Int)' = 1.86x10^{15}, \( r^2 = 0.94 \), from which the four kinetic rate constants \( k_1, k_-1, k_2, k_-2 \) the formation constants \( K_1 = k_1/k_-1 \), \( K_2 = k_2/k_-2 \) and the dimerization constant \( K_q = K_1(1+K_2) \) have been calculated (Table III).

A second approximation has been performed using \( K_q = 20M^{-1} \) to calculate \( c_p = (\text{AB}) \).
The new sequence gives Slope = 6.74x10^9, Int = 2.02x10^8, r^2 = 0.93 for S vs c, but (Slope)' = 9.49x10^7, (Int)' = 0, r^2 = 0.60 for I vs c making impossible further progress without a reliable figure for Kq.

For lithium thiocyanate in THF, a single Debye process suffices to interpret the ultrasonic relaxation data. The infrared data indicate that the contact species (LiNCS)_2 are in minor concentration (as well as the assigned triple ion species), the major species being the "spectroscopically free" LiNCS pair. The latter maybe a combination of LiNCS and (LiNCS...LiNCS) species.

Consequently we have interpreted the ultrasonic spectra for lithium thiocyanate in THF as due to the process

\[
\frac{k_f}{k_r} \quad 2 \text{LiNCS} \xrightleftharpoons{} (\text{LiNCS...LiNCS})
\]

where the product of the reaction maybe mainly (LiNCS...LiNCS) with a minor percentage of contact (LiNCS)_2. Both species will be symbolized here as (LiNCS...LiNCS). Notice in fact from Table II that the visible relaxation frequency for lithium thiocyanate solutions 0.1M (f_r = 60MHz) is comparable with f_1 = 70 MHz for sodium thiocyanate solutions 0.1M, whereas f_II = 7MHz. Scheme IV, leads to the relation

\[
\tau^{-1} = 4k_f(\text{LiNCS}) + k_r = 4k_f(AB) + k_r
\]

with

\[
K_1 = \frac{(AB)_2}{(AB)^2} = k_f/k_r \quad (AB)_2 = (\text{LiNCS} \cdots \text{LiNCS})
\]

By calling in zeroth approximation (AB) = c, linear regression of \(\tau^{-1}\) vs c gives

r^2 = 0.97, slope = 1.96x10^8, Int = 1.85x10^8, from which one calculates

k_f = 4.6x10^8 M^{-1}s^{-1}, k_r = 1.85x10^8 s^{-1}, K_1 = 2.65 M^{-1}. (Fig10)
A series of successive approximations is started with the initial 
\( K_1 = 2.6 \text{M}^{-1} \). After seven approximations convergence is obtained with 
\( K_1 = 6.6 \text{M}^{-1}, k_f = 9.9 \times 10^8 \text{M}^{-1} \text{s}^{-1}, k_r = 1.5 \times 10^8 \text{s}^{-1} \).

Notice that the zeroth approximation \( k_0 = 4.9 \times 10^8 \text{M}^{-1} \text{s}^{-1} \) is comparable with the value of \( k_1 = 3.4 \times 10^8 \text{M}^{-1} \text{s}^{-1} \) calculated for sodium thiocyanate in THF, reinforcing the above interpretation of the ultrasonic relaxation of lithium thiocyanate leading mainly to outersphere dimers.

Conclusions

The combination of vibrational spectrometry and ultrasonic spectrometry in electrolyte solutions of low permittivity, leads to complementary information of invaluable importance in the interpretation of the relaxation spectra by ultrasonics. Instead of guessing the species participating the chemical equilibria being disturbed by the sound wave, one has indication of their presence by infrared spectra in a comparable concentration range. On the other hand, as any other method, vibrational spectra seem to have limitations in their apparent inability to distinguish between “free species” and “solvent separated species” leading to interpretation errors if one ignores the possible presence of the latter ones.

Work is now in progress with other lithium electrolytes more likely to be employed in solutions used for battery construction.

List of Figures

Fig. 1 Representative infrared spectra for the "CN" stretch of sodium thiocyanate in THF at various concentrations.

Fig. 2 Representative infrared spectrum for the "CN" stretch of lithium thiocyanate in THF.

Fig. 3 Digitized infrared spectrum and calculated spectrum sum of three Gaussian-Lorentzian product functions for sodium thiocyanate in THF. Cell length \( \ell = 0.057 \text{mm} \).

Fig. 4 Digitized Infrared spectrum and calculated spectrum sum of three Gaussian-Lorentzian product functions for lithium thiocyanate in THF. Cell length \( \ell = 0.058 \text{mm} \).

Fig. 5 Excess sound absorption per wavelength \( \mu \) vs. frequency \( f \) for a representative ultrasonic spectrum of sodium thiocyanate in THF at 25°C.

Fig. 6 Excess sound absorption per wavelength \( \mu \) vs. frequency \( f \) for a representative ultrasonic spectrum of lithium thiocyanate in THF at 25°C.

Fig. 7 Maximum absorbances vs. concentration of the Gaussian-Lorentzian bands for sodium thiocyanate in THF.

Fig. 8 Maximum absorbances vs. concentration of the Gaussian-Lorentzian bands for lithium thiocyanate in THF.

Fig. 9a \( S(=\tau_1^{-1} + \tau_2^{-1}) \) vs. \( c \) for sodium thiocyanate in THF at 25°C.

Fig. 9b \( P(=\tau_1^{-1} \times \tau_2^{-1}) \) vs. \( c \) for sodium thiocyanate in THF at \( t = 25°C \).

Fig. 10 \( \tau^{-1} \) vs. \( c \) for lithium thiocyanate in THF at \( t = 25°C \).
Infrared Spectrum of LiSCN 0.21M in THF
Digitized Infrared Spectrum for NaSCN 0.198 M in THF

Solid line is the sum of three Gaussian - Lorentzian product functions:

\[ A = \Sigma_i A_i^0 \exp \left(-\frac{(\tilde{\nu} - \tilde{\nu}_i)^2}{2\sigma_i^2}\right) \left[1 + \frac{(\tilde{\nu} - \tilde{\nu}_i)^2}{\sigma_i^2}\right]^{-1} \]

Parameters:

\[ \tilde{\nu}_1 = 2043.5 \text{ cm}^{-1} \]
\[ A_1^0 = 0.79 \]
\[ \tilde{\nu}_2 = 2057 \text{ cm}^{-1} \]
\[ A_2^0 = 0.47 \]
\[ \tilde{\nu}_3 = 2074 \text{ cm} \]
\[ A_3^0 = 0.10 \]

\[ (\Delta \nu_1)_{1/2} = (\Delta \nu_2)_{1/2} = (\Delta \nu_3)_{1/2} = 13 \text{ cm}^{-1} \]

\[ \sigma_i = \frac{(\Delta \nu_i)_{1/2}}{1.46} (i = 1, 2, 3) \]
Digitized Infrared Spectrum for
LiSCN 0.21M in THF

Solid line is the sum of three Gaussian - Lorentzian product functions:

\[ A = \sum_i A_i^0 \exp \left[-\frac{(\bar{\nu} - \bar{\nu}_i)^2}{2\sigma_i^2}\right] \left[1 + \frac{(\bar{\nu} - \bar{\nu}_i)^2}{\sigma_i^2}\right]^{-1} \]

Parameters:

- \( \bar{\nu}_1 = 2040 \text{ cm}^{-1} \)
- \( \bar{\nu}_2 = 2065 \text{ cm}^{-1} \)
- \( \bar{\nu}_3 = 2086 \text{ cm}^{-1} \)
- \( A_1^0 = 0.14 \)
- \( A_2^0 = 1.26 \)
- \( A_3^0 = 0.12 \)
- \( (\Delta \nu_i)_{1/2} = 14 \text{ cm}^{-1} (i = 1,2,3) \)
- \( \sigma_i = \frac{(\Delta \nu_i)_{1/2}}{1.46} \)
NaSCN 0.158M in THF
$t = 25^\circ C$

$\mu_1 = 260 \times 10^{-5}$
$f_1 = 80 \text{MHz}$
$\mu_2 = 35 \times 10^{-5}$
$f_2 = 10 \text{MHz}$
$B = 124 \times 10^{-17} \text{ cm}^{-1} \text{s}^2$
$u = 1.304 \times 10^5 \text{ cm/s}$
LiSCN 0.10M in THF

$\mu_m = 370 \times 10^{-5}$

$f_r = 60 \text{MHz}$

$B = 112 \times 10^{-17} \text{cm}^{-1} \text{s}^2$

$u = 1.282 \times 10^5 \text{cm} \text{s}^{-1}$
Absorbances per unit length $A_{\nu_i}^0/\ell$
of the Gaussian Lorentzian functions vs. concentration
for NaSCN in THF

($\ell$ = length of infrared cell)
Absorbances per unit length $A^0_{\nu_1}/\ell$
of the Gaussian-Lorentzian functions vs. concentration for LiSCN in THF

($\ell =$ length of infrared cell)
$S = (\tau^{-1}_I + \tau^{-1}_II)$ vs. $C_0$ for NaSCN in THF, $t = 25^\circ C$

$P = (\tau^{-1}_I \times \tau^{-1}_II)$ vs. $C_0$ for NaSCN in THF, $t = 25^\circ C$
$\tau^{-1} \text{ vs. } C_p$ for LiSCN in THF at $t = 25^\circ C$

$$C_p = \frac{-1 + \sqrt{1 + 8KqCo}}{4Kq}$$
