19. **ABSTRACT (Continue on reverse if necessary and identify by block number)**

A modal expansion technique is applied to a system of uniform waveguides interconnected by abrupt junctions. Computer codes developed for the asymmetrical modes on-axis transition and all modes off-axis transition have been tested and verified through two separate experimental verifications.

The three main parts of this work are:

a. The tentative formulation for an abrupt transition from one waveguide to another, where each junction is restricted to having only one input and one output waveguide, while a conducting wall on each side of the junction is accounted for;

b. The development of convergence criteria for the selection of the important modes via symmetry used in each waveguide section.

All other editions are obsolete.
c. The numerical implementation of the evaluation of the coupling coefficients for the coupling cases:

On-axis asymmetrical modes (circular to circular, circular to coaxial, and coaxial to coaxial waveguide transitions). Off-axis for all modes (circular to circular, circular to coaxial, and coaxial to coaxial waveguide transitions).

The implementation of this formulation requires modification of the structure of the matrix equation of the existing code. To expand the capability and the versatility of the code, future work should include the implementation of ridged waveguide, dielectric loaded waveguide, and multiport junctions.
ACKNOWLEDGEMENTS

Credit is long overdue to many people both for their help in bringing this work to its completion and for their support in shaping my career in microwave engineering.

I am particularly indebted to Dr. Peter Rizzi, my undergraduate Professor in Electrical Engineering at Southeastern Massachusetts University, who initially interested me in this discipline and who encouraged me to first apply to the AFTER Program. I would also like to thank Mr. Paul Cleary for his help in arranging my entrance to the Program. And of course, I owe thanks to the Raytheon Power Tube Division and the U.S. Air Force for the learning opportunity they afforded me through their joint sponsorship of the AFTER Program.

Many thanks are due to Professors R. Grow, J. M. Baird and others at the University of Utah who taught the many invaluable courses which prepared me for this project. I am very much indebted to Dr. A. Palevsky, my thesis adviser, for his guidance and assistance throughout the various stages of this work, and to Dr. N. Dionne for contributing the initial idea of this thesis topic.

I am most grateful for the talented assistance in drawing generously provided by Mr. J. L. Rousseau. I also gratefully acknowledge the time and care spent by Maureen T. Connaughton and Donald R. Dacier who were responsible for typing and drafting the manuscript.

Last but not least, I must thank my family, especially my wife Barbara Anne, for their full support and encouragement during these long years of graduate study.

I. INTRODUCTION

Waveguide discontinuity problems are very common to microwave engineering. Various approaches for different type of waveguide transitions have been developed including the conventional lumped equivalent circuits and field theory techniques\textsuperscript{1,3}. Following the approach of Clarricoats\textsuperscript{1} which is a field theory technique led to more detailed work and numerical applications by Mielke\textsuperscript{4}. In brief, this technique involves matching the normal mode expansions in each waveguide section at the junction between sections. A large matrix equation is obtained which is then solved for mode amplitudes. Transmission coefficients, reflection coefficients, and power flow are calculated in terms of these amplitudes. Mielke's original work only allowed an abrupt transitions from one waveguide to another. Within this junction, two additional restrictions are imposed. One is that each junction can have only one input and one output waveguide. Second is that the smaller waveguide must lie entirely within the boundaries of the larger waveguide. Within this framework, the following coupling coefficient calculations have been obtained analytically and implemented in a computer code:

- on-axis symmetrical modes (circular to circular, circular to coaxial, and coaxial to coaxial waveguide transitions)
- on-axis and off-axis for all modes (rectangular to rectangular waveguide transition)

Subsequent work on circular to rectangular waveguide transition case has been implemented numerically by Palevsky\textsuperscript{5}. 

The first part of the work presented is to introduce a tentative formulation which is able to handle the transition problem of the type that permits a conducting wall on each side of the junction. However, the junction is still restricted to be an abrupt transition from one waveguide to another. Also each junction is still allowed to have only one input and one output waveguide. The modal expansion technique is again applied here. This formulation is not yet implemented and its derivation is described in Chapter II.

The second part of this work is the development of the convergence criteria. Accurate results depend critically upon judicious choice of the important modes via symmetry used in each waveguide section. Ideally, an infinite number of modes should be used. In practice, truncation errors caused by use of a finite number of modes can be reduced if these modes are wisely selected. Criteria for such selections are derived.

The third aspect of this thesis is to implement the evaluations of the coupling coefficients for the following cases:

- on-axis asymmetrical modes (circular to circular, circular to coaxial, and coaxial to coaxial waveguide transitions)
- off-axis for all modes (circular to circular, circular to coaxial, and coaxial to coaxial transitions)

The numerical implementation of the above cases is done following the technique developed for the circular to rectangular waveguide transition.
II. FORMULATION

The transition which has a transverse conducting wall on each side of the junction is investigated. The coaxial to coaxial transition as shown in Figure 2-1b which maintains the same characteristic impedance is a common transition that requires this extended formulation. A number of different geometries of a two-sided boundary transition is illustrated in Figure 2-1.

Adopt the definition of expressing the transverse electromagnetic fields in the expansion of an infinite number of vector mode functions found in Reference 3. For a junction which has an input guide 1 and an output guide 2, the fields in both guides are matched at the junction.

The boundary conditions require that:

in the common cross-sectional area (aperture)

\[ \mathbf{E}_t^i (1) = \mathbf{E}_t (2) \quad (2-1) \]

\[ \mathbf{H}_t^i (1) = \mathbf{H}_t (2) \quad (2-2) \]

and on the left side of the conducting wall

\[ \mathbf{E}_t^i (1) = 0 \quad (2-3) \]

and on the right side of the conducting wall

\[ \mathbf{E}_t (2) = 0 \quad (2-4) \]
Figure 2-1. Two-Sided Boundary Transitions.
Two useful pairs of equations may be derived from equations (2-1) and (2-2) by manipulating either (2-3) or (2-4).

First scalar multiply equations of (2-1) and (2-3) by

\[
\sum_{k_1'} \bar{e}(k_1,1) \]

\[
\vec{E}_\hat{t}(1) \cdot \sum_{k_1'} \bar{e}(k_1,1) = \vec{E}_\hat{t}(2) \cdot \sum_{k_1'} \bar{e}(k_1,1) \quad (2-5)
\]

in the aperture

\[
\vec{E}_\hat{t}(1) \cdot \sum_{k_1'} \bar{e}(k_1,1) = 0 \quad (2-6)
\]

on the left side of the conducting wall

Where \(\bar{e}(k_1,1)\) are basis vector mode functions in region 1 and \(N(1)\) is number of modes used in the expansion.

Secondly post vector multiply equation (2-2) by \(\sum_{k_2'} \bar{e}(k_2,2)\),

\[
\vec{H}_\hat{t}(1) \times \sum_{k_2'} \bar{e}(k_2,2) = \vec{H}_\hat{t}(2) \times \sum_{k_2'} \bar{e}(k_2,2) \quad (2-7)
\]

in the aperture

Where \(\bar{e}(k_2,2)\) are basis vector mode functions in region 2 and \(N(2)\) is number of modes used in the expansion.

Integrating (2-5) over the aperture, added to the integration of (2-6)

over the left conducting wall gives:

\[
\int \int \vec{E}_\hat{t}(1) \cdot \sum_{k_1'} \bar{e}(k_1,1) \, ds = \int \int \vec{E}_\hat{t}(2) \cdot \sum_{k_1'} \bar{e}(k_1,1) \, ds \quad (2-8a)
\]

Integration of (2-7) over the aperture yields:

\[
\int \int \left[ \vec{H}_\hat{t}(1) \times \sum_{k_2'} \bar{e}(k_2,2) \right] \cdot ds = \int \int \left[ \vec{H}_\hat{t}(2) \times \sum_{k_2'} \bar{e}(k_2,2) \right] \cdot ds \quad (2-9a)
\]
The use of the symmetric manipulations leads to the following dual equations (2-8) and (2-9):

\[ \int_1^2 \left[ \int_{A(1,2)} H_t(1) \times \sum_{k_1} \bar{e}(k_1, 1) \right] ds = \int_1^2 \left[ \int_{A(1,2)} H_t(2) \times \sum_{k_1} \bar{e}(k_1, 1) \right] ds \]  

(2-8b)

\[ \int_1^2 \left[ \int_{A(1,2)} E_t(1) \times \sum_{k_2} \bar{e}(k_2, 2) \right] ds = \int_1^2 \left[ \int_{A(1,2)} E_t(2) \times \sum_{k_2} \bar{e}(k_2, 2) \right] ds \]  

(2-9b)

Where \( \text{cs}(1), \text{cs}(2) \) are cross-sectional area of guides 1 and 2 and \( A(1,2) \) the common cross-sectional area at the junction between guides 1 and 2. Since both sets of equations should give the same solutions in the limit of an infinite number of modes, any linear combination should also give the same solutions. How these two sets of equations should be weighted in a linear combination is discussed in detail in Appendix A. The combined equations (2-8a + 2-8b) and (2-9a + 2-9b) form the matrix equation which is solved for the forward mode amplitudes and the backward mode amplitudes. The size of the matrix will increase as the number of modes per region and the number of regions increase.

To set up the large matrix equation, the coupling terms and the propagation terms must be calculated. The one-sided boundary transition formulation contains coupling terms that are integrals of two modes, one from each side of the junction, over the aperture (Overlap Integrals). The two-sided boundary transition formulation contains additional coupling terms that are integrals of two modes, both from the same waveguide, over the aperture (Cross-Overlap Integrals).
Whereas the propagation terms are the same for both transitions. To include this type of transition into the existing system of equation of the one-sided boundary problem, the entries of the matrix structure as well as the entries of the known subvectors have to be modified. The very detailed structure of the matrix equation is given in Appendix A.
III. NUMERICAL CONVERGENCE CRITERIA

There are always solutions to the matrix equation. However, unless sufficient modes in both regions preceding and following any junction are considered, the solutions will be inaccurate. The accuracy can be estimated, in principle, by examining the transverse fields at the junction.

This is done by adding all the transverse fields in region preceding the junction to obtain the total field and subtracting the summation of all the transverse fields following the junction. The result will indicate how close the fields in both regions are matched at the junction. However, this is a cumbersome process. Therefore, another technique is developed which provides a way of estimating the accuracy of the solutions.

Figure 3-1 illustrates the longitudinal view of a single junction.

![Diagram of longitudinal view of a single junction]

Figure 3-1. Longitudinal View of a Single Junction.
The transverse vector mode functions of guides $j$ and $j+1$ are given by:

\[
\overline{e} (k_j, j) \quad \text{for guide } j
\]

\[
\overline{e} (k_{j+1}, j+1) \quad \text{for guide } j+1
\]

The overlap and self-overlap integrals are defined by:

\[
0.1. \ (k_j, k_{j+1}, j) = \int \overline{e} (k_j, j) \cdot \overline{e} (k_{j+1}, j+1) \, ds \quad (3-1)
\]

\[
A(j, j+1)
\]

\[
S.0.I. \ (k_j, j) = \int \overline{e} (k_j, j) \cdot \overline{e} (k_j, j) \, ds \quad (3-2)
\]

\[
A(j, j+1)
\]

\[
S.0.I. \ (k_{j+1}, j) = \int \overline{e} (k_{j+1}, j+1) \cdot \overline{e} (k_{j+1}, j+1) \, ds \quad (3-3)
\]

\[
A(j, j+1)
\]

First consider a given single incident mode in larger guide $j$. Due to the discontinuity, an infinite number of modes in guide $j+1$ are excited. This incident mode over the smaller cross section can be represented at the junction by:

\[
\overline{e} (k_j, j) = \lim_{N(j+1) + \infty} \sum_{k_{j+1}, j+1 = 1}^{N(j+1)} a (k_{j+1}, j+1) \cdot \overline{e} (k_{j+1}, j+1) \quad (3-4)
\]

Where $a (k_{j+1}, j+1)$ is a weighting factor of each excited mode in guide $j+1$. Substitution of $(3-4)$ into $(3-1)$ yields:

\[
0.1. \ (k_j, k_{j+1}, j) = \lim_{N(j+1) + \infty} \sum_{k_{j+1}, j+1 = 1}^{N(j+1)} a (k_{j+1}, j+1)
\]

\[
A(j, j+1)
\]

\[
\int \overline{e} (k_{j+1}, j+1) \cdot \overline{e} (k_{j+1}, j+1) \, ds \quad (3-5)
\]

\[
A(j, j+1)
\]
Application of the orthogonality of the normal mode properties, (3-5) becomes:

$$\text{O.I. } (k_j, k_{j+1}, j) = \begin{cases} a(k_{j+1}, j+1) & \text{if } k_{j+1} = k_j+1 \\ 0 & \text{if } k_{j+1} \neq k_j+1 \end{cases}$$  \hspace{1cm} (3-6)

Hence, (3-4) becomes:

$$\overline{a}(k_j, j) = \lim_{N(j+1)} \sum_{k_{j+1}=1}^{N(j+1)} \text{O.I. } (k_j, k_{j+1}, j) \cdot \overline{a}(k_{j+1}, j+1)$$  \hspace{1cm} (3-7)

Substitution of (3-7) into (3-2) yields:

$$\text{S.O.I. } (k_j, j) = \lim_{N(j+1)} \sum_{k_{j+1}=1}^{N(j+1)} \left\{ \text{O.I. } (k_j, k_{j+1}, j) \right\}^2 \cdot \int_{A(j, j+1)} \overline{a}(k_{j+1}, j+1) \cdot \overline{a}(k_{j+1}, j+1) \, ds$$  \hspace{1cm} (3-8)

or,

$$\text{S.O.I. } (k_j, j) = \lim_{N(j+1)} \sum_{k_{j+1}=1}^{N(j+1)} \left\{ \text{O.I. } (k_j, k_{j+1}, j) \right\}^2$$  \hspace{1cm} (3-9)

Secondly consider a single mode in the smaller guide $j+1$ incident on the junction, with an infinite number of modes are excited in guide $j$. This incident mode over the large cross section can be represented by:

$$\overline{a}(k_{j+1}, j+1) = \lim_{N(j)} \sum_{k_j=1}^{N(j)} b(k_j, j) \cdot \overline{a}(k_j, j)$$  \hspace{1cm} (3-10)

Where $b(k_j, j)$ is a weighting factor of each reflected mode in guide $j$. Substitution of (3-10) into (3-1) yields:

$$\text{O.I. } (k_j, k_{j+1}, j) = \lim_{N(j)} \sum_{k_j=1}^{N(j)} b(k_j, j) \cdot \int_{A(j, j+1)} \overline{a}(k_j, j) \cdot \overline{a}(k_j, j) \, ds$$  \hspace{1cm} (3-11)
or, 

\[ O.I. \ (k_j, k_{j+1}, j) = \begin{cases} b \ (k_j, j) & \text{if } k_j = k_j \\ 0 & \text{if } k_j \neq k_j \end{cases} \quad (3-12) \]

Hence, (3-10) becomes:

\[ \bar{e} (k_{j+1}, j+1) = \lim_{N(j) \to \infty} \sum_{k_j=1}^{N(j)} O.I. \ (k_j, k_{j+1}, j) \cdot \bar{e} (k_j, j) \quad (3-13) \]

Substitution of (3-13) into (3-3) yields:

\[ \iint_{cs(j+1)} \bar{e} (k_{j+1}, j+1) \cdot \bar{e} (k_{j+1}, j+1) \, ds = \lim_{N(j) \to \infty} \sum_{k_j=1}^{N(j)} \left\{ O.I. \ (k_j, k_{j+1}, j) \right\}^2 \]

or,

\[ 1 = \lim_{N(j) \to \infty} \sum_{k_j=1}^{N(j)} \left\{ O.I. \ (k_j, k_{j+1}, j) \right\}^2 \quad (3-15) \]

Equations (3-9) and (3-15) are indicators for the completeness of the total representation of an infinite number of modes accountable for both transverse electromagnetic fields in guide \( j \) and \( j+1 \).

**For the first case:**

\[ 0 \leq \frac{\sum_{k_j+1}^{N(j+1)} \left\{ O.I. \ (k_j, k_{j+1}, j) \right\}^2}{S.O.I. \ (k_j, j)} \leq 1.0 \quad (3-9) \]

**For the second case:**

\[ 0 \leq \sum_{k_j=1}^{N(j)} \left\{ O.I. \ (k_j, k_{j+1}, j) \right\}^2 \leq 1.0 \quad (3-15) \]
Therefore the convergence can be verified by including a sufficient number of high order modes in both regions preceding and following the junction until the calculated value of equations (3-9) and (3-15) reaches roughly 95% or higher.

The knowledge of the field patterns of different modes for various geometries is helpful in choosing the correct modes for convergence. The number of modes required for convergence varies depending on the ratio of the cross-sectional areas of the two guides, the amount of offset, and the similarity of geometry. For example, two rectangular guides of only slightly different dimensions will require only a few modes to obtain good convergence. However, a rectangular to circular junction with offset axes and a large difference in cross-sectional area will take many modes to achieve good convergence.
IV. NUMERICAL EVALUATION OF OVERLAP AND SELF-OVERLAP INTEGRALS FOR CIRCULAR AND COAXIAL GEOMETRIES

For a one-sided boundary transition, the closed form solutions of the overlap and self-overlap integrals for the symmetrical modes on-axis transition are available in Reference 4, whereas for the asymmetrical modes on-axis and for all the modes off-axis transition have not yet been obtained analytically. Therefore, they must be evaluated numerically. The overlap and self-overlap integrals for the asymmetrical modes on-axis transition which are dependent only on the radial coordinate are evaluated in one dimension, while the overlap and self-overlap integrals for all the modes off-axis transition are evaluated in two dimensions.

The IMSL$^6$ routines DCADRE and DBLIN are used for one and two dimension integrations respectively. DCADRE is a routine of one dimension numerical integration of a function using cautious adaptive Romberg extrapolation; where DBLIN is a two dimensional version of DCADRE applying the same numerical approach. The routines require as inputs the limits of integration and the value of the integrand as a function of position. The remainder of this chapter describes how these two items are calculated.

Since the radial dependent part of the mode vector functions are expressed in terms of Bessel functions, an explicit evaluation of the functions in the integrands is computationally expensive. Therefore, a spline routine is used to fit the radial dependent part of the mode vector functions, and spline interpolation is used to evaluate it in the integrand. The IMSL$^6$ routines ICSICU and ICSEVU are used for the fitting and interpolation. Eight steps (radial increment) per wavelength plus four steps at each end point are used in the spline fit to guarantee a smooth interpolation.
The center of the input guide is adopted as a reference frame for the evaluation of the integral.

A. **Overlap Integral of an On-Axis Transition**

The following derivation is valid for the on-axis circular/coaxial transitions. The transitions for various geometries are shown in Figure 4-1.

The overlap integral is given by:

$$0.1. (k_j, k_{j+1}, j) = \iint A(J, j+1)$$

Substituting the mode functions listed in Appendix C into the above integral, it yields:

$$0.1. (k_j, k_{j+1}, j) = \iint \left[ E \psi (k_j, j, r) \cdot E \psi (k_{j+1}, j+1, r) \cdot P \psi (k_j, k_{j+1}, \psi) ight] r dr \cdot d \psi$$

Where $E \psi (k_j, j, r)$, $E \psi (k_{j+1}, j+1, r)$ are radial dependent parts of the radial electric fields, and $E \psi (k_j, j, r)$, $E \psi (k_{j+1}, j+1, r)$ are radial dependent parts of the azimuthal electric fields. Since the integral of the product of polarization terms for radial electric fields is the same as the integral of the product of polarization terms for azimuthal electric fields, the integral is represented by $P (k_j, k_{j+1}, \psi)$.

Upon factoring the r and $\psi$ components, (4-2) becomes:

$$0.1. (k_j, k_{j+1}, j) = \left\{ \int E \psi (k_j, j, r) \cdot E \psi (k_{j+1}, j+1, r) + E \psi (k_j, j, r) \cdot E \psi (k_{j+1}, j+1, r) \cdot r dr \right\} \cdot P (k_j, k_{j+1}, \psi)$$

(4-3)
Figure 4-1. One-Sided Boundary On-Axis Transition.
The integral \( P(k_{j}, k_{j+1}, \psi) \) is evaluated for different modes coupling and the results are listed in Table 4-1. Obviously, the polarization factors for mode couplings of the different azimuthal mode number are equal to zero. The remaining task is to numerically integrate the radial part of integrand. The limits for the radial integral are simply the extreme boundaries of the common cross-sectional area at the junction.

\( \Delta \theta \) is an angular rotation of the secondary axes relative to the main frame axes.

B. Overlap Integral of an Off-Axis Transition

The off-axis transition involves the integration of a function of two variables. The integration is always performed in the cartesian coordinate system of the first region \( j \). The relationship between the two coordinate systems is illustrated in Figure 4-2. \( \Delta x, \Delta y, \) and \( \Delta \theta \) are the offset of the guide \( j+1 \) relative to the guide \( j \), and \( \Delta \theta \) is applied after \( \Delta x \) and \( \Delta y \).
Figure 4-2. Cross Section View of the Two Coordinate Systems.
The vector mode functions in guides $j$ and $j+1$ can be written in terms of their cylindrical coordinates as:

\[
\begin{align*}
\mathbf{e} (k_j, j) &= E_r (k_j, j, r) \cdot p (k_j, j, \psi) \cdot \hat{r}_o + \\
&\quad E_\psi (k_j, j, r) \cdot q (k_j, j, \psi) \cdot \hat{\psi}_o \\
\mathbf{e} (k_{j+1}, j+1) &= E_r' (k_{j+1}, j+1, r') \cdot p (k_{j+1}, j+1, \psi') \cdot \hat{r}'_o + \\
&\quad E_\psi' (k_{j+1}, j+1, r') \cdot q (k_{j+1}, j+1, \psi') \cdot \hat{\psi}_o
\end{align*}
\]

(4-4)

Where $\hat{r}_o$, $\hat{\psi}_o$ are unit vectors along $r$ and $\psi$ directions; and $\hat{r}'_o$, $\hat{\psi}'_o$ are unit vectors along $r'$ and $\psi'$ directions. The expressions $p (k_j, j, \psi)$, $q (k_j, j, \psi)$ and $p (k_{j+1}, j+1, \psi')$, $q (k_{j+1}, j+1, \psi')$ are polarization terms of guides $j$ and $j+1$ respectively.

Using the following coordinate transformation,

\[
\begin{align*}
x &= r \cdot \cos \psi - \psi \cdot \sin \psi \\
y &= r \cdot \sin \psi - \psi \cdot \cos \psi
\end{align*}
\]

(4-5)

the transverse fields of guide $j$ evaluated at a local point $A$ are given in the cartesian coordinate system (reference frame) as:

\[
\begin{align*}
E_x (k_j, j)|_A &= [E_r (k_j, j, r) \cdot p (k_j, j, \psi)]|_A \cdot \cos \psi_A - \\
&\quad [E_\psi (k_j, j, r) \cdot q (k_j, j, \psi)]|_A \cdot \sin \psi_A \\
E_y (k_j, j)|_A &= [E_r (k_j, j, r) \cdot p (k_j, j, \psi)]|_A \cdot \sin \psi_A + \\
&\quad [E_\psi (k_j, j, r) \cdot q (k_j, j, \psi)]|_A \cdot \cos \psi_A
\end{align*}
\]

(4-6)
Where at point A, \( r_A \) and \( \psi_A \) are given by:

\[
\begin{align*}
  r_A &= \sqrt{x_A^2 + y_A^2} \\
  \psi_A &= \tan^{-1} \frac{y_A}{x_A}
\end{align*}
\]

(4-7)

At the same point A, the coordinate transformation from the second guide to the first guide is given by:

\[
\begin{align*}
  x_1 &= x_A - \Delta x \\
  y_1 &= y_A - \Delta y \\
  r' &= \sqrt{x_1^2 + y_1^2} \\
  \psi_1 &= \tan^{-1} \frac{y_1}{x_1} \\
  \psi' &= \psi_1 - \Delta \theta \\
  &= \tan^{-1} \frac{y_A'}{x_A'}
\end{align*}
\]

(4-8)

Applying the coordinate transformation of (4-5), the transverse fields of guide \( j+1 \) expressed in terms of the reference coordinate system are:

\[
\begin{align*}
  E_x (k_{j+1}, j+1) &= \{ E_{r'} (k_{j+1}, j+1, r') \cdot p (k_{j+1}, j+1, \psi') \} \cdot \cos \psi_1 - \\
  &\quad \{ E_{\psi'} (k_{j+1}, j+1, r') \cdot q (k_{j+1}, j+1, \psi') \} \cdot \sin \psi_1 \\
  E_y (k_{j+1}, j+1) &= \{ E_{r'} (k_{j+1}, j+1, r') \cdot p (k_{j+1}, j+1, \psi') \} \cdot \sin \psi_1 + \\
  &\quad \{ E_{\psi'} (k_{j+1}, j+1, r') \cdot q (k_{j+1}, j+1, \psi') \} \cdot \cos \psi_1
\end{align*}
\]

(4-9)
Equation (4-1) becomes:

\[ O.I. (k_j, k_{j+1}, j) = \iiint \left\{ E_x (k_j, j) \cdot E_x (k_{j+1}, j+1) + E_y (k_j, j) \cdot E_y (k_{j+1}, j+1) \right\} \cdot dx \, dy \]  

(4-10)

The limits of the integration of the above integral are derived below for various transitions and geometries.

Bl. **Circular to Circular Transition**

Figure 4-3 illustrates the cross section view of the junction.

![Cross Section View](image-url)

*Figure 4-3. Cross Section View of Circular to Circular Transition.*
The lower and upper limits of the horizontal end points are found to be:

\[ x_{\text{lower}} = -a_{j+1} + \Delta x \]
\[ x_{\text{upper}} = +a_{j+1} + \Delta x \] (4-11)

While the limits of the vertical end points are given by:

\[ y_{\text{lower}}(x) = \Delta y - \sqrt{\frac{2}{a_{j+1} - (x - \Delta x)^2}} \] (4-12)
\[ y_{\text{upper}}(x) = \Delta y + \sqrt{\frac{2}{a_{j+1} - (x - \Delta x)^2}} \]

B2. Coaxial to Coaxial Transition

The cross section view of the junction is depicted in Figure 4-4. The limits of the horizontal end points are:

\[ x_{\text{lower}} = -a_{j+1} + \Delta x \]
\[ x_{\text{upper}} = +a_{j+1} + \Delta x \] (4-13)

The common cross-sectional area is exactly the area bounded by the inner and the outer walls of guide j+1. For simplicity, the annular aperture is divided into two regions of integration. Figure 4-5 shows the top half annular ring, where the dashed line indicates the upper bound and the solid line indicates the lower bound of the region of integration.
Figure 4-4. Cross Section View of Coaxial to Coaxial Transition.
Figure 4-5. Top Half Annular Aperture.

For the top half:

\[
\begin{align*}
Y_{\text{lower}}(x) &= \begin{cases} 
\Delta y & \text{for } |x - \Delta x| \geq b_{j+1} \\
\Delta y + \sqrt{b_{j+1}^2 - (x - \Delta x)^2} & \text{for } |x - \Delta x| < b_{j+1}
\end{cases} \\
Y_{\text{upper}}(x) &= \Delta y + \sqrt{a_{j+1}^2 - (x - \Delta x)^2}
\end{align*}
\]

(4-14)

The bottom half annular aperture is illustrated in Figure 4-6.
Figure 4-6. Bottom Half Annular Aperture.

For the bottom half:

\[
y_{\text{lower}}(x) = \Delta y - \sqrt{a_{j+1} - (x - \Delta x)^2} 
\]

\[
y_{\text{upper}}(x) = \begin{cases} 
\Delta y & \text{for } |x - \Delta x| \geq b_{j+1} \\
\Delta y - \sqrt{b_{j+1} - (x - \Delta x)^2} & \text{for } |x - \Delta x| < b_{j+1}
\end{cases}
\]

(4-15)
B3. **Circular to Coaxial Transition**

Since the area of integration is bounded by the inner and outer walls of coaxial guide, the limits for both horizontal and vertical end points are the same as the previous case. The same techniques are used to numerically evaluate the self-overlap integrals.
V. EXPERIMENTAL VERIFICATION

The computer code developed for asymmetrical modes of the on-axis and the off-axis transitions has been tested with two separate configurations. The two dimension numerical integration code was tested by verifying the measured return loss (reflection) of an off-axis transition. The one dimension numerical integration code was tested by comparing the experimental results of the return loss of a centered circular aperture of finite thickness (obtained from Reference 3) to the numerical results.

The ratio of the cross-sectional areas of the two guides at the junction determines the preliminary guess of the ratio of the number of modes considered in each guide at that junction. Mode selection for limiting the choices of modes in the expansion to those which strongly affect the wave solution was done by observing the strength of the coupling between each higher order mode and the dominant mode. The convergence criteria was satisfied in all cases. Violation of this criteria yielded inaccurate results.

A. Three Regions Off-Axis Circular to Circular Transition

An illustration of the three regions transition is depicted in Figure 5-1. Two units of the transition were fabricated. The dimensions for each unit are listed in Table 5-1. Notice that the only difference between the two units is that the length of the middle region which is of 11.0 mm for unit A, and 15.0 mm for unit B.

A block diagram of the experimental arrangements for the reflection measurement is illustrated in Figure 5-2. The equipment used for the setup is listed in Table 5-2. Calibration for 100% reflection was done by placing the shorting plate at the output of
Figure 5-1. Three Regions Off-Axis Circular to Circular Transition.

the mode filter. Since a high quality matched load was not available, the reflection measurement was performed by leaving the output end of the transition open to air. This was treated as an 18 dB of return loss in the code since the average measured return loss of the unterminated transition was approximately 18 dB across the entire frequency band.

The first calculated return losses which are obtained with no input reflections considered are not in good agreement with the measured results. They are shown in Figure 5-3 for Unit A, and in Figure 5-4 for Unit B. We theorized that this might be due to the mode filter not absorbing higher order reflected modes excited at the junction between the mode filter and mode converter. To take this into account, the overall length of the first region preceding the transition was adjusted and an input reflection of 50% was added in the computer code after a number of runs. The results of the measured and the calculated return losses of the two units are shown in Figures 5-5 and 5-6 respectively. The calculated curves for both units follow the measured curves closely across the frequency band. At the lowest end of the band which is near the cutoff frequency of the dominant mode (TE_{11} mode), the calculated return loss is higher than the measured return loss for Unit A. The ripples observed across the midband for Unit A and uniformly across the entire band for Unit B are probably caused by the imperfection of the mode filter.

B. Centered Circular Aperture of Finite Thickness in Circular Guide

A small centered circular aperture in a transverse metallic plate of finite thickness (TE_{11} mode in circular guide) in circular
Figure 5-3. Measured and Calculated Reflection for Unit A (with No Input Reflection).

Figure 5-5. Measured and Calculated Reflection for Unit A (with 50% Input Reflection).
guide may be interpreted as a shunt inductance. The cross sectional view, the side view, and the equivalent circuit are illustrated in Figure 5-7. At the reference plane $T$ for a centered circular aperture, the normalized inductive susceptance is given by

$$\frac{B}{Y_0} = \frac{\lambda g}{4R} \left[ \frac{(2R)^3}{8.40 M} - 2.344 \right]$$

(5-1)

where

$$M = \frac{d^3}{6}$$

(5-2)

$$\lambda g = \frac{\lambda}{\left[ 1 - \left( \frac{\lambda}{3.412R} \right)^2 \right]^{1/2}}$$

(5-3)

the reflection coefficient can be expressed in term of $\frac{B}{Y_0}$ as:

$$\rho = \frac{1}{2} \left| \frac{B}{Y_0} \right| \left[ 1 + \frac{\left( \frac{B}{2Y_0} \right)^2}{\left( \frac{B}{2Y_0} \right)^2 + 1} \right]^{1/2}$$

(5-4)

and the return loss in dB is,

$$\text{return loss} = -20 \log_{10} (\rho)$$

(5-5)

Measurements of the return loss taken at $\lambda = 3.20$ cm in a circular guide of $\frac{15}{16}$ in. diameter and the centered aperture metallic plate of $\frac{1}{32}$ in. thickness with various sizes of diameter of the aperture are shown in Figure 5.5-3 in Reference 3, Section 5.5 page 243 to 246 in term of $\frac{B}{Y_0}$. In the computer code, the circular aperture of finite thickness is modeled as a circular guide with smaller diameter than the main guide, and its length is the thickness of the aperture. This is a three regions on-axis circular to circular transition. The
Figure 5-7. Centered Circular Aperture of Finite Thickness in Circular Guide.
diameter of 23.812 mm and the length of 100.0 mm are the dimensions of the first and the last regions. The length of the middle region is 0.794 mm, and the diameter varies from 6.35 mm to 23.019 mm. The model of the transition is depicted in Figure 5-8. The theoretical and the experimental results extrapolated from the graphs (Figure 5.5-3) in Reference 3 are compared to the numerical results and listed in Table 5-3.

Disregarding the results at the point size aperture and at the limit of the size of the aperture approaching the size of the main guide, the experimental and the numerical results agree very well within the average of +2.5 dB and −0.04 dB. Where at the point size aperture, it is seen that the numerical result is about 0.009 dB less than the experimental result. The probable cause is an insufficient number of higher order modes in the modal expansion. It can be explained that a point size aperture which can be interpreted as a Dirac delta function has a spatial Fourier representation of an infinite sum of harmonic components where the modal expansion technique starts to break down. Likewise, at the limit of the size of the aperture approaching the size of the guide, the numerical result is roughly 11 dB higher than the experimental result. It suggested that for this low scale of VSWR's reading, the measured data obtained from Reference 3 was inaccurate. This is perhaps due to the insensitivity of the equipment available at that time. Also 36 dB and 47 dB are equivalent to 1.6% and 0.45% reflection coefficient respectively. This error is less than 1.2% in absolute terms.

Note that the ratio in dB is defined as \(-20 \log_{10} \frac{P_{\text{Numerical}}}{P_{\text{Experimental}}}\).
VI. CONCLUSION

The modal expansion technique was found to be capable of handling any system of uniform waveguides interconnected by abrupt junctions. The computer codes developed for the asymmetrical modes on-axis transition and all modes off-axis transition have been tested and verified through two separate experimental verifications. The results obtained are satisfactory. Also, the numerical convergence criteria has been tested. Violation of the criteria has been shown of giving inaccurate solutions. Formulation of the two-sided boundary transition has been derived. The implementation of this formulation requires modification of the structure of the matrix equation of the existing code. To expand the capability and the versatility of the code, future work should also include the implementation of ridged waveguide, dielectric loaded waveguide and multiport junctions.
Appendix A: Derivation of the Matrix Equation

A very detailed derivation of matrix equations of a two-sided boundary junction is presented in this appendix. This generalized transition has conducting boundary on both sides of the junction. The transition discussed in Reference 4 was restricted to only one side of having a conducting wall.

A single junction of two-sided boundary is illustrated in Figure A-1.

Figure A-1. Longitudinal View of a Two-Sided Boundary Off-Axis Transition.
The guide $j$ represents the input guide and the guide $j+1$ is the output guide. The junction is viewed as one transition of possibly many transitions preceding the guide $j$ and following the guide $j+1$. In general, one source term per mode is allowed anywhere along the length of each section. Figure A-2 shows the forward going wave, the backward going wave, and the source term of a single region $j$.

![Diagram](image)

**Figure A-2.** A Single Region $j$ Showing the Forward Going Wave, the Backward Going Wave, and the Source.
The forward mode amplitude, $F$, and the backward mode amplitude, $B'$, are the response of this cavity to the defined source terms $F_s$ and $B_s$. These terms $F$ and $B'$ are the solutions to the matrix equation discussed in Chapter II.

The fields at any location along any waveguide region can be expressed in terms of the sum of orthogonal functions weighed by their respective mode amplitudes and propagation terms.

For a single junction as shown in Figure A-1, the total transverse electromagnetic fields are given,

At the input plane of guide $j+1$:

$$\tilde{E}_t^{(j+1)} = \sum_{k_{j+1}=1}^{N(j+1)} \left( F (k_{j+1}, j+1) + B (k_{j+1}, j+1) + B_s (k_{j+1}, j+1) \right) \cdot e_{(k_{j+1}, j+1)}$$  \hspace{1cm} (A-1)

$$\tilde{H}_t^{(j+1)} = \sum_{k_{j+1}=1}^{N(j+1)} \frac{1}{Z(k_{j+1}, j+1)} \left( F (k_{j+1}, j+1) - B (k_{j+1}, j+1) - B_s (k_{j+1}, j+1) \right) \cdot h_{(k_{j+1}, j+1)}$$  \hspace{1cm} (A-2)

At the output plane of guide $j$:

$$\tilde{E}_t' (j) = \sum_{k_j=1}^{N(j)} \left( F' (k_j, j) + B' (k_j, j) + F_s' (k_j, j) \right) \cdot e_{(k_j, j)}$$  \hspace{1cm} (A-3)

$$\tilde{H}_t' (j) = \sum_{k_j=1}^{N(j)} \frac{h_{(k_j, j)}}{Z(k_j, j)} \left( F' (k_j, j) - B' (k_j, j) + F_s' (k_j, j) \right)$$  \hspace{1cm} (A-4)

Where $K_j, K_{j+1}$ are mode indices for an arbitrary set of $N(j), N(j+1)$ modes.
At the junction, the transverse fields of the two regions must be matched at various areas. Let $cs(j)$ and $cs(j+1)$ be the cross-sectional area of regions $j$ and $j+1$ respectively. And $A(j, j+1)$ is the common cross-sectional area at the junction $j$ between regions $j$ and $j+1$. In the common cross-sectional area:

$$E_t'(j) = E_t'(j+1) \quad (A-5)$$

$$H_t'(j) = H_t'(j+1) \quad (A-6)$$

On the left side of the conducting wall:

$$E_t'(j) = 0 \quad (A-7)$$

On the right side of the conducting wall:

$$E_t'(j+1) = 0 \quad (A-8)$$

Two possible pairs of equations may be derived from equations (A-5) and (A-6) by using either (A-7) or (A-8). To cast the equations in a more useful form, the following manipulations are used. First consider the use of (A-7). Scalar vector multiplication of equations (A-5) and (A-7) by $\sum_{k_j' = 1}^{N(j)} e(k_j', j)$ yields:

$$E_t'(j) \cdot \sum_{k_j' = 1}^{N(j)} e(k_j', j) = E_t'(j+1) \cdot \sum_{k_j' = 1}^{N(j)} e(k_j', j) \quad (A-9)$$

(in the aperture)

$$E_t'(j) \cdot \sum_{k_j' = 1}^{N(j)} e(k_j', j) = 0 \quad (A-10)$$

(on the left conducting wall)
Post vector multiplication of equation (A-6) by \( \sum_{k_j+1=1}^{N(j+1)} \bar{e} (k_{j+1}, j+1) \) yields:

\[
\hat{H}_T (j) \times \sum_{k_j+1=1}^{N(j+1)} \bar{e} (k_{j+1}, j+1) = \hat{H}_T (j+1) \times \sum_{k_j+1=1}^{N(j+1)} \bar{e} (k_{j+1}, j+1) \quad (A-11)
\]

(in the aperture)

The integration of equation (A-9) over the common cross-sectional area, added to the integration of equation (A-10) over the left conducting wall gives:

\[
\int_{\text{cs}(j)}^{N(j)} \bar{E}_T' (j) \cdot \sum_{k_j=1}^{N(j)} \bar{e} (k_j, j) \, ds = \int_{\text{A}(j, j+1)}^{N(j)} \bar{E}_T (j+1) \cdot \sum_{k_j=1}^{N(j)} \bar{e} (k_j, j) \, ds \quad (A-12)
\]

The integration of equation (A-11) over the common cross-sectional area yields:

\[
\int_{\text{A}(j, j+1)}^{N(j+1)} \left[ \hat{H}_T' (j) \times \sum_{k_j+1=1}^{N(j+1)} \bar{e} (k_{j+1}, j+1) \right] \cdot ds = \int_{\text{A}(j, j+1)}^{N(j+1)} \left[ \hat{H}_T (j+1) \times \sum_{k_j+1=1}^{N(j+1)} \bar{e} (k_{j+1}, j+1) \right] \cdot ds \quad (A-13)
\]

Substituting (A-1), (A-2), (A-3), and (A-4) into (A-12) and (A-13) gives:

\[
\sum_{k_j=1}^{N(j)} \sum_{k_j'=1}^{N(j)} \left\{ F' (k_j, j) + B' (k_j, j) + F_s' (k_j, j) \right\} \cdot \int_{\text{cs}(j)}^{N(j)} \bar{e} (k_j, j) \cdot \bar{e} (k_j, j) \, ds = \quad (A-12)
\]

\[
\sum_{k_j'=1}^{N(j+1)} \sum_{k_j+1=1}^{N(j+1)} \left\{ F (k_{j+1}, j+1) + B (k_{j+1}, j+1) + B_s (k_{j+1}, j+1) \right\} \cdot \int_{\text{A}(j, j+1)}^{N(j+1)} \bar{e} (k_{j+1}, j+1) \cdot \bar{e} (k_{j+1}, j+1) \, ds \quad (A-12)
\]
\[ \sum_{k_j=1}^{N(j)} \sum_{k'_j+1=1}^{N(j+1)} \frac{1}{Z(k_j, j)} \left[ F' (k_j, j) - B' (k_j, j) + F_s' (k_j, j) \right] \cdot \int_{A(j, j+1)} \left[ \overline{h} (k_j, j) \times \overline{e} (k'_j, j+1) \right] \cdot d\overline{s} = \int_{A(j, j+1)} \left[ \overline{h} (k_j, j+1) \times \overline{e} (k'_j+1, j+1) \right] \cdot d\overline{s} \]
\[ \sum_{j=1}^{N(j)} \sum_{k_j=1}^{N(j)} \frac{O.I. (k_j, k_{j+1}, j)}{Z (k_j, j)} \left\{ F' (k_j, j) - B' (k_j, j) + F_s' (k_j, j) \right\} = \]

\[ \sum_{j=1}^{N(j)} \sum_{k_j=1}^{N(j)} \frac{O.I. (k_j, k_{j+1}, j)}{Z (k_j, j)} \left\{ F (k_{j+1}, j+1) - B (k_{j+1}, j+1) - B_s' (k_{j+1}, j+1) \right\} \]

\[ \sum_{j=1}^{N(j)} \sum_{k_j=1}^{N(j)} \frac{C.O.I. (k_{j+1}, k_j, j)}{Z (k_{j+1}, j)} \left\{ F (k_{j+1}, j+1) - B (k_{j+1}, j+1) - B_s (k_{j+1}, j+1) \right\} \]

Second consider the use of (A-8). Using completely the symmetric manipulations, the following dual to equations (A-12a) and (A-13a)

\[ \sum_{j=1}^{N(j)} \sum_{k_j=1}^{N(j)} \frac{C.O.I. (k_j, k_{j'}, j)}{Z (k_j, k_{j'})} \left\{ F' (k_j, j) - B' (k_j, j) + F_s' (k_j, j) \right\} = \]

\[ \sum_{j=1}^{N(j)} \sum_{k_j=1}^{N(j)} \frac{O.I. (k_j, k_{j+1}, j)}{Z (k_j, j+1)} \left\{ F (k_{j+1}, j+1) - B (k_{j+1}, j+1) - B_s (k_{j+1}, j+1) \right\} \]

Both pair of the equations (A-12a), (A-13a), and (A-12b), (A-13b) can be written in matrix form as:

\[ M_\alpha \bar{x} = \bar{b}_\alpha \]

Where \( \alpha = a \) or \( b \)
The matrix $M_\alpha$, vectors $\overline{x}$ and $\overline{b}_\alpha$ are shown in Figure A-3. Where the submatrices and subvectors are shown in Figures A-4 through A-16. For the case of single, two, and J junctions, the structures of the matrix equations are shown in Figures A-17 through A-19.

Both these sets of equations should have the same solution in the limit of an infinite number of modes. The similarity of these equations to the single sided boundary equations derived in Reference 4 is demonstrated. First examine the equations (A-12a) and (A-13a) in the limit of the area of the right wall going to zero.

Since,

$$\lim_{\text{area of right wall} \to 0} \int_{A(j, j+1)} e^{(k_j+1, j+1)} \cdot e^{(k_{j+1}, j+1)} \, ds = \frac{1}{A(j, j+1)}$$

$$\int_{A(j, j+1)} e^{(k_j+1, j+1)} \cdot e^{(k_{j+1}, j+1)} \, ds = \frac{1}{cs(j+1)}$$

$$= \begin{cases} 1 & \text{if } k_{j+1} = k_j+1 \\ 0 & \text{if } k_{j+1} \neq k_j+1 \end{cases} \quad (A-15)$$

Then, equations (A-12a) and (A-13a) become a pair of equations derived for larger-to-smaller transition defined in Reference 4. Similarly, it can be shown that in the limit of the area of the left wall going to zero, the equations (A-12b) and (A-13b) are equivalent to another pair of equations derived for smaller-to-larger transition in Reference 4.

Since both sets of equations should yield the same result, any linear combination should also yield the same result. It is expected that the solutions to the equations (A-12a) and (A-13a) should converge...
Equation (A12 α) in Matrix Form:

\[
\begin{bmatrix}
M_{j,j} & 0 \\
0 & M_{j+1,j+1}
\end{bmatrix}
\begin{bmatrix}
x_j \\
x_{j+1}
\end{bmatrix}
= 
\begin{bmatrix}
b_j
\end{bmatrix}
\]

Equation (A13 α) in Matrix Form:

\[
\begin{bmatrix}
M_{j+1,j} & 0 \\
0 & M_{j+1,j+1}
\end{bmatrix}
\begin{bmatrix}
x_j \\
x_{j+1}
\end{bmatrix}
= 
\begin{bmatrix}
b_{j+1}
\end{bmatrix}
\]

\end{array}
\]
Figure A-19. J Junctions Matrix.
faster to the correct solutions as the number of modes per region is increased for junctions that have most of the conducting wall on the left side. Similarly one would expect the solutions to equations (A-12b) and (A-13b) to converge more rapidly to the right answers for junctions with most of the conducting wall on the right side of the boundary. Therefore, it would seem reasonable to make a linear combination of equations (A-12a), (A-13a) and (A-12b), (A-13b) where each term is weighted by the relative area of the conducting wall on each side.

Thus,

\[ \omega_L * M_a \overline{x} = \omega_L * \overline{b}_a \]  
\[ \omega_R * M_b \overline{x} = \omega_R * \overline{b}_b \]  

(A-16)

Where \( \omega_L \) and \( \omega_R \) are defined by:

\[ \omega_L = \frac{\text{area of left wall}}{\text{area of left wall} + \text{area of right wall}} \]  
\[ \omega_R = \frac{\text{area of right wall}}{\text{area of left wall} + \text{area of right wall}} \]  

(A-17)

After combining, it yields:

\[ \{ \omega_L * M_a + \omega_R * M_b \} \overline{x} = \omega_L * \overline{b}_a + \omega_R * \overline{b}_b \]  

(A-18)

Where the submatrices and subvectors of (A-18) are shown in Figures A-20 through A-26 for a single junction.

The backward mode reflection coefficient for the first region that generates a forward going wave in the first region (not a source term) is normally defined for a given problem. Similarly, the forward mode reflection coefficient for the last region that generates a backward going wave in that last section is also a known quantity.

Figure A-26. Solution Subvectors.
This is equivalent to defining the input and output termination of the problem. Therefore, the structure of the matrix equation for junctions (J+1 regions) is modified as shown in Figure A-27; where the modified submatrices and solution subvectors are shown in Figures A-28 through A-32.

Figure A-32. Modified First and Last Region Solution Subvectors.
Appendix B: Derivation of the Self-Overlap Integrals for Symmetrical Modes of Circular and Coaxial Geometries On-Axis Transition

The criteria for the convergence check established in Chapter III requires a knowledge of the values of the self-overlap integrals of every mode accounted for at the junction. The area of integration is always the common cross-sectional aperture. The self-overlap integral for any mode in the smaller guide is trivially unity. Therefore, only the self-overlap integral for a mode in the larger guide over the common aperture is derived.

The S.O.I. for any mode $k_j$ in the larger cross section guide $j$ is defined by

$$S.O.I. (k_j, j) = \int_{A(j, j+1)} \overline{e}(k_j, j) \cdot \overline{e}(k_j, j) \, ds \quad (B-1)$$

The closed form solutions of the self-overlap integrals for the symmetrical ($m=0$) modes on-axis transition are derived below for various waveguide geometries.

B.I. Circular to Circular Transition

The longitudinal view of the transition is depicted in Figure B-1. From the Appendix C, the TE mode vector function in guide $j$ with $k_j$ representing $m = 0$ and arbitrary $n$ is given by:

$$e_{TE}(k_j, j) = \sqrt{\frac{1}{n}} \frac{J_0(x_{on}) \cdot r_j}{a_j \cdot J_0(x_{on})} \cdot r_0 \quad (B-2)$$

Where $n = 1, 2, 3, \ldots$ and $x_{on}$ is the nth zero of $J_0$.
Figure B-1. Longitudinal View of Circular to Circular Transition.
Substitution of (B-2) into (B-1) yields:

\[ S.O.I. \left( k_j, j \right) = \int_0^{2\pi} \int_0^{a_j+1} \left\{ \sqrt{\frac{1}{w}} \cdot \frac{J_0' \left( \frac{r}{x_{on} \cdot a_j} \right)}{a_j \cdot J_0 \left( x_{on} \right)} \right\}^2 \cdot rdr \, d\psi \]  

(B-3)

Application of the derivative formula of Bessel function:

\[ J_i' \left( x \right) = -J_{i+1} \left( x \right) \]

And with the use of the integrals of Bessel functions formula (4) on page 255 in Reference 2, (B-3) becomes

\[ S.O.I. \left( k_j, j \right) = \left( \frac{a_j+1}{a_j} \right)^2 \cdot \frac{J_1 \left( x_{on} \cdot a_j \right) - J_0 \left( x_{on} \cdot a_j \right) \cdot J_2 \left( x_{on} \cdot a_j \right)}{J_0 \left( x_{on} \right)} \]  

(B-4)

For TM mode with \( k_j \) representing \( m=0 \) and arbitrary \( n \), the vector mode function is:

\[ e^{-\left( k_j \cdot x \right)} = -\sqrt{\frac{1}{w}} \cdot \frac{J_0' \left( x_{on} \cdot a_j \right)}{a_j \cdot J_1 \left( x_{on} \right)} \cdot r_0 \]  

(B-5)

Where \( x_{on} \) is the \( n \)th zero of \( J_0 \)

Substitution of (B-5) into (B-1) gives:

\[ S.O.I. \left( k_j, j \right) = \int_0^{2\pi} \int_0^{a_j+1} \left\{ -\sqrt{\frac{1}{w}} \cdot \frac{J_0' \left( x_{on} \cdot a_j \right)}{a_j \cdot J_1 \left( x_{on} \right)} \right\}^2 \cdot rdr \, d\psi \]  

(B-6)

Evaluating the integration yields:

\[ S.O.I. \left( k_j, j \right) = \left( \frac{a_j+1}{a_j} \right)^2 \cdot \frac{J_1 \left( x_{on} \cdot a_j \right) - J_0 \left( x_{on} \cdot a_j \right) \cdot J_2 \left( x_{on} \cdot a_j \right)}{J_1 \left( x_{on} \right)} \]  

(B-7)
B.2. Coaxial to Coaxial Transition

The type of transition (one-sided boundary) as shown in Figure B-2 is valid for the derivations below. For the case of $k_j$ representing $m=0$ and arbitrary $n$, the TE mode vector function is:

$$\frac{\text{TE}}{e} (k_j, j) = \frac{x_{on}}{b_j} \cdot \frac{\sqrt{x}}{2} \cdot \frac{J_0' \left( x_{on} \cdot \frac{r}{b_j} \right) - N_0' \left( x_{on} \cdot \frac{r}{b_j} \right)}{J_0' \left( x_{on} \right) - N_0' \left( x_{on} \cdot \frac{r}{b_j} \right)} \cdot J_0' \left( x_{on} \right) \cdot r \cdot dr \quad (B-8)$$

Substituting (B-8) into (B-1) and collecting terms yields:

$$\text{S.O.I.} (k_j, j) = \left( \frac{x_{on}}{b_j} \right)^2 \cdot \frac{\pi^2}{2} \cdot \int_{b_j+1}^{a_j+1} \left\{ J_0' \left( x_{on} \cdot \frac{r}{b_j} \right) \right\} \cdot \left\{ J_0' \left( x_{on} \cdot \frac{a_j}{b_j} \right) - 1 \right\} \cdot \left\{ J_0' \left( x_{on} \cdot \frac{a_j+1}{b_j} \right) \right\} \cdot r \cdot dr \quad (B-9)$$

Evaluating the integral yields:

$$\text{S.O.I.} (k_j, j) = \frac{\pi^2}{4} \left\{ J_0' \left( x_{on} \cdot \frac{a_j+1}{b_j} \right) \right\} \left( \frac{x_{on}}{b_j} \cdot \frac{a_j+1}{b_j} \right)^2 \cdot \left\{ J_1 \left( x_{on} \cdot \frac{a_j+1}{b_j} \right) \right\}$$

$$\cdot N_1 \left( x_{on} \cdot \frac{a_j+1}{b_j} \right) \cdot J_1 \left( x_{on} \right) \right\}^2 - \left\{ N_0 \left( x_{on} \cdot \frac{a_j+1}{b_j} \right) \right\} \cdot J_1 \left( x_{on} \right)$$
Figure B-2. One-Sided Boundary Coaxial to Coaxial Transition.
\[ J_0 \left( x_{on} \cdot \frac{a_{j+1}}{b_j} \right) \cdot N_1 \left( x_{on} \right) - \left( N_2 \left( x_{on} \cdot \frac{a_{j+1}}{b_j} \right) \cdot J_1 \left( x_{on} \right) - J_2 \left( x_{on} \cdot \frac{a_{j+1}}{b_j} \right) \right) \]

\[ N_1 \left( x_{on} \cdot \frac{b_{j+1}}{b_j} \right) \cdot J_1 \left( x_{on} \right) - \left( N_0 \left( x_{on} \cdot \frac{b_{j+1}}{b_j} \right) \cdot J_1 \left( x_{on} \right) - J_0 \left( x_{on} \cdot \frac{b_{j+1}}{b_j} \right) \right) \cdot N_1 \left( x_{on} \right) - \]

For TM mode with \( k_j \) representing \( m=0 \) and arbitrary \( n \), the vector mode function is:

\[ e^{-\text{TM}} \left( k_j, j \right) = \frac{x_{on}}{b_j} \frac{\sqrt{x_{on}}}{2} J_0 \left( x_{on} \cdot \frac{r}{b_j} \right) \cdot N_0 \left( x_{on} \right) - N_0 \left( x_{on} \cdot \frac{r}{b_j} \right) \cdot J_0 \left( x_{on} \right) \]

\[ \left\{ \begin{array}{c} J_0 \left( x_{on} \right) \\ J_0 \left( x_{on} \cdot \frac{r}{b_j} \right) \end{array} \right\} \frac{1}{2} \left( J_0 \left( x_{on} \right) - 1 \right) \]

Substitution (B-11) into (B-1) gives:

S.O.I. \( (k_j, j) = \int_0^{2\pi} \int_{b_j}^{b_{j+1}} \left\{ \frac{x_{on}}{b_j} \cdot \sqrt{\frac{x_{on}}{2}} \cdot J_0 \left( x_{on} \cdot \frac{r}{b_j} \right) \cdot N_0 \left( x_{on} \right) - N_0 \left( x_{on} \cdot \frac{r}{b_j} \right) \cdot J_0 \left( x_{on} \right) \right\} \]

\[ \left\{ \begin{array}{c} J_0 \left( x_{on} \right) \\ J_0 \left( x_{on} \cdot \frac{r}{b_j} \right) \end{array} \right\} \frac{1}{2} \left( J_0 \left( x_{on} \right) - 1 \right) \]
Evaluating the integration yields:

$$S.O.I. (k_j, j) = \frac{\pi^2}{4} \left[ \frac{J_0^2 (x_{on})}{J_0^2 (x_{on} \frac{a_j+1}{b_j})} - 1 \right] \left\{ \left( x_{on} - \frac{a_j+1}{b_j} \right)^2 \left[ N_1 (x_{on} \frac{a_j+1}{b_j}) \right] \right\}$$

$$J_0 \left( x_{on} \frac{a_j+1}{b_j} \right) - J_1 \left( x_{on} \frac{a_j+1}{b_j} \right) \cdot N_o \left( x_{on} \right)^2 - \left\{ N_0 \left( x_{on} \frac{a_j+1}{b_j} \right) \cdot J_0 \left( x_{on} \right) - \right\}$$

$$J_0 \left( x_{on} \frac{b_j+1}{b_j} \right) \cdot N_o \left( x_{on} \right)^2 - \left( x_{on} \frac{b_j+1}{b_j} \right)^2 \left[ \left( x_{on} \frac{b_j+1}{b_j} \right) \cdot J_0 \left( x_{on} \right) - J_2 \left( x_{on} \frac{a_j+1}{b_j} \right) \right]$$

$$N_o \left( x_{on} \right)_\frac{b_j+1}{b_j} \cdot J_0 \left( x_{on} \right) - J_1 \left( x_{on} \frac{b_j+1}{b_j} \right)$$

For TEM mode with $k_j$ representing $m=0$ and $n=0$, the vector mode function is:

$$\hat{e}^{TEM} (k_j, j) = \frac{-1}{r \cdot \sqrt{2\pi \ln \left( \frac{a_j}{b_j} \right)}} \cdot \hat{r}_o \quad (B-14)$$

Equation (B-1) becomes:

$$S.O.I. (k_j, j) = \int_0^{2\pi} \int_0^{a_j+1} \left\{ \frac{-1}{r \cdot \sqrt{2\pi \ln \left( \frac{a_j}{b_j} \right)}} \right\}^2 r \, dr \, d\psi \quad (B-15)$$
Evaluating the integration yields:

\[
\text{S.O.I. } (k_j,j) = \frac{\ln \left( \frac{a_j+1}{b_j+1} \right)}{2 \ln \left( \frac{a_j}{b_j} \right)} \quad (B-16)
\]

**B.3. Circular to Coaxial Transition**

The derivation below is valid for a smaller coaxial guide totally embedded inside a larger circular waveguide. Such a transition is depicted in Figure B-3.

With \(k_j\) representing \(m=0\) and arbitrary \(n\), the vector mode functions for a circular guide are given in (B-2) and (B-5) above. Performing the integration over the annular aperture yields expressions of S.O.I. For TE mode:

\[
\text{S.O.I. } (k_j,j) = \frac{1}{J_o^2(x_{on})} \cdot \left\{ \left( \frac{a_j+1}{a_j} \right)^2 \left[ J_1^2 \left( x_{on} \cdot \frac{a_j+1}{a_j} \right) - J_0 \left( x_{on} \cdot \frac{a_j+1}{a_j} \right) \right] - \left( \frac{b_j+1}{b_j} \right)^2 \left[ J_1^2 \left( x_{on} \cdot \frac{b_j+1}{b_j} \right) - J_0 \left( x_{on} \cdot \frac{b_j+1}{b_j} \right) \right] \right\}
\]

Where \(x_{on}\) is the \(n\)th zero of \(J_0^\prime\).
Figure B-3. One-Sided Boundary Circular to Coaxial Transition.
For TM mode:

$$S.O.I. \ (k_j, j) = \frac{1}{J_1^2 (x_{on})} \cdot \left\{ \left( a_j + 1 \right)^2 \cdot \left[ J_1^2 \left( x_{on} \cdot \frac{a_j + 1}{a_j} \right) - J_0 \left( x_{on} \cdot \frac{a_j + 1}{a_j} \right) \right] \right\} \cdot \left\{ \left( b_j + 1 \right)^2 \cdot \left[ J_1^2 \left( x_{on} \cdot \frac{b_j + 1}{a_j} \right) - J_0 \left( x_{on} \cdot \frac{b_j + 1}{a_j} \right) \right] \right\}$$

Where $x_{on}$ is the nth zero of $J_0$.

All the above integrals are evaluated with the aid of the integrals of Bessel functions formula (4) on page 255 in Reference 2.
Appendix C: Vector Mode Functions for TE, TM, and TEM Mode for Rectangular, Circular, and Coaxial Geometries

The transverse fields for the rectangular, circular, and coaxial waveguides are derived in Reference 3. The formulas for the TE, TM, and TEM modes are given below. The origin of the coordinates have been moved to the center of the guide from the lower left hand corner for the rectangular waveguide modes. The vector mode functions are represented by

\[ e_{mn} = \text{TM mode vector function} \]

\[ e_{mn} = \text{TE mode vector function} \]

\[ e_{00} = \text{TEM mode vector function (coaxial guide only)} \]

For a rectangular waveguide, the cross section view is depicted in Figure C-1.

Figure C-1. Cross Section View of a Rectangular Waveguide.
The TM, and TE vector mode functions for a rectangular waveguide

are given by

\[
\frac{\text{TM}}{e_{mn}} = \frac{-2}{\sqrt{a^2 b + c^2}} \left\{ \left[ \frac{m\pi}{a} \cos \frac{m\pi}{a} (x + \frac{a}{2}) \cdot \sin \frac{n\pi}{b} (y + \frac{b}{2}) \right] \cdot \hat{x}_0 + \left[ \frac{n\pi}{b} \sin \frac{m\pi}{a} (x + \frac{a}{2}) \cdot \cos \frac{n\pi}{b} (y + \frac{b}{2}) \right] \cdot \hat{y}_0 \right\} \tag{C-1}
\]

\[
\frac{\text{TE}}{e_{mn}} = \sqrt{\frac{\varepsilon_m \varepsilon_n}{\pi}} \frac{2}{\sqrt{a^2 b + c^2}} \left\{ \left[ \frac{m\pi}{b} \cos \frac{m\pi}{a} (x + \frac{a}{2}) \cdot \sin \frac{n\pi}{b} (y + \frac{b}{2}) \right] \cdot \hat{x}_0 - \left[ \frac{m\pi}{a} \sin \frac{m\pi}{a} (x + \frac{a}{2}) \cdot \cos \frac{n\pi}{b} (y + \frac{b}{2}) \right] \cdot \hat{y}_0 \right\} \tag{C-2}
\]

Where \( \hat{x}_0, \hat{y}_0 \) are unit vectors along x and y - axis respectively.

\[ e_m = \begin{cases} 1 & \text{if } m = 0 \\ 2 & \text{if } m \neq 0 \end{cases} \]

Figure C-2 illustrates the cross section view of a circular waveguide.
The TM mode vector function for a circular waveguide is:

\[
\mathbf{E}_{mn}^{TM} = -\sqrt{\frac{\varepsilon_m}{\varepsilon_m}} \frac{1}{J_{m+1}(x_{mn})} \left\{ \left[ \frac{1}{r} \cdot J_m(x_{mn} \cdot \frac{r}{a}) \cdot \begin{bmatrix} \cos \psi \\ \sin \psi \end{bmatrix} \right] \cdot \hat{r}_o + \left[ \frac{m}{r \cdot x_{mn}} \cdot J_m(x_{mn} \cdot \frac{r}{a}) \cdot \begin{bmatrix} -\sin \psi \\ \cos \psi \end{bmatrix} \right] \cdot \hat{\psi}_o \right\} \] (C-3)

The TE mode vector function for a circular waveguide is:

\[
\mathbf{E}_{mn}^{TE} = \sqrt{\frac{\varepsilon_m \cdot \pi \cdot J_m(x_{mn})}{\varepsilon_m}} \left\{ \left[ \frac{m}{r} \cdot J_m(x_{mn} \cdot \frac{r}{a}) \cdot \begin{bmatrix} \sin \psi \\ -\cos \psi \end{bmatrix} \right] \cdot \hat{r}_o + \left[ \frac{x_{mn}}{a} \cdot J_m(x_{mn} \cdot \frac{r}{a}) \cdot \begin{bmatrix} \cos \psi \\ \sin \psi \end{bmatrix} \right] \cdot \hat{\psi}_o \right\} \] (C-4)

Where \( \hat{r}_o, \hat{\psi}_o \) are unit vectors along \( r \) and \( \psi \) directions.

\[ m = 0, 1, 2, ... \]
\[ n = 1, 2, 3, ... \]
\[ x_{mn} = \text{nth non-vanishing root of the mth \text{-} order Bessel function } J_m(x_{mn}) = 0 \]
\[ x_{mn}' = \text{nth non-vanishing root of the derivative of the mth \text{-} order Bessel function } J'_m(x_{mn}) = 0 \]

\[ \varepsilon_m = \begin{cases} 1 & \text{if } m = 0 \\ 2 & \text{if } m \neq 0 \end{cases} \]

For a coaxial waveguide, the cross section view is shown in Figure C-3.
Figure C-3. Cross Section View of a Coaxial Waveguide.
The TM mode vector function for a coaxial waveguide is:

\[
\frac{-\mathbf{TM}_{e_{mn}}}{\omega_{mn}^2} = -\frac{\sqrt{\mu_{\epsilon_{mn}}}}{2} \left\{ \left( \frac{x_{mn} \cdot \mathbf{r}}{b} \right) N_m'(x_{mn}) - N_m'(x_{mn} \cdot \mathbf{r}/b) J_m'(x_{mn}) \right\}.
\]

\[
\left[ \begin{array}{c} \cos \psi_m \\ \sin \psi_m \end{array} \right] \cdot \hat{\mathbf{r}} = \left\{ \left( \frac{x_{mn} \cdot \mathbf{r}}{b} \right) N_m'(x_{mn}) - N_m'(x_{mn} \cdot \mathbf{r}/b) J_m'(x_{mn}) \right\}.
\]

\[
\left[ \begin{array}{c} \sin \psi_m \\ \cos \psi_m \end{array} \right] \cdot \mathbf{\hat{z}}_o
\]

The TE mode vector function for a coaxial waveguide is:

\[
\frac{-\mathbf{TE}_{e_{mn}}}{\omega_{mn}^2} = \frac{\sqrt{\mu_{\epsilon_{mn}}}}{2} \left\{ \left( \frac{x_{mn} \cdot \mathbf{r}}{b} \right) N_m'(x_{mn}) - N_m'(x_{mn} \cdot \mathbf{r}/b) J_m'(x_{mn}) \right\}.
\]

\[
\left[ \begin{array}{c} \sin \psi_m \\ \cos \psi_m \end{array} \right] \cdot \hat{\mathbf{r}} = \left\{ \left( \frac{x_{mn} \cdot \mathbf{r}}{b} \right) N_m'(x_{mn}) - N_m'(x_{mn} \cdot \mathbf{r}/b) J_m'(x_{mn}) \right\}.
\]

\[
\left[ \begin{array}{c} \cos \psi_m \\ \sin \psi_m \end{array} \right] \cdot \mathbf{\hat{z}}_o
\]
And the TEM mode vector function is:

\[
\vec{e}_{oo}^{\text{TEM}} = -\frac{1}{r \sqrt{2\pi \ln \left(\frac{a}{b}\right)}} \cdot \hat{r}_o \quad (C-7)
\]

Where \( \hat{r}_o, \hat{\psi}_o \) are unit vectors along \( r \) and \( \psi \) directions

\[
m = 0, 1, 2, 3, ...
\]

\[
n = 1, 2, 3, ...
\]

\[
c = \frac{a}{b}
\]

\[
x_{mn} = \text{nth non-vanishing root of the } m \text{- order Bessel-Neumann combination.}
\]

\[
x_{mn} = \text{nth non-vanishing root of the derivative of the } m \text{- order Bessel-Neumann combination}
\]

\[
\varepsilon_m = \begin{cases} 
1 & \text{if } m = 0 \\
2 & \text{if } m \neq 0
\end{cases}
\]

LIST OF SYMBOLS (Continued)

\( cs (j) \) Cross-sectional area of region \( j \)

\( d (k,j) \) Distance of the location of excited source mode \( k \) from input plane of region \( j \)

\( e (k,j) \) Vector mode function of mode \( k \) region \( j \)

\( \_TM \ e (k_j,j) \) TM mode vector function of mode \( k_j \) region \( j \)

\( \_TE \ e (k_j,j) \) TE mode vector function of mode \( k_j \) region \( j \)

\( \_TEM \ e (k_j,j) \) TEM mode vector function of mode \( k_j \) region \( j \)

\( \dot{E}_t (j), \dot{E}_t (j) \) Total input and output transverse electric fields representation of guide \( j \)

\( E_r (k_j, j, r) \) The radial dependent part of the radial electric field magnitude of mode \( k_j \) in region \( j \)

\( E_\psi (k_j, j, r) \) The radial dependent part of the azimuthal electric field magnitude of mode \( k_j \) in region \( j \)

\( F (k,j) \) Forward mode \( k \) of \( \dot{E} \) field magnitude defined at input plane of region \( j \)

\( F' (k,j) \) Forward mode \( k \) of \( \dot{E} \) field magnitude defined at output plane of region \( j \) \( (= F (k,j) \cdot G_f (k,j)) \)

\( F_s (k,j) \) Component of forward mode \( k \) of \( \dot{E} \) field magnitude defined at distance \( d (k,j) \) from the input plane of region \( j \) due to source terms

\( F_s (k,j) \) Component of forward mode \( k \) of \( \dot{E} \) field magnitude defined at the output plane of region \( j \) due to source terms \( = F_s (k,j) \cdot G_{fs} (k,j) \)

LIST OF SYMBOLS (Continued)

\[ P(k_j, k_{j+1}, \psi) \]
Integral of the product of the polarization terms
\[ = \int_0^{2\pi} \mathbf{p}_{r}(k_j, k_{j+1}, \psi) \cdot d\psi = \int_0^{2\pi} \mathbf{p}_{\psi}(k_j, k_{j+1}, \psi) \cdot d\psi \]

\[ P_r(k_j, k_{j+1}, \psi) \]
Product of the polarization terms
\[ = \mathbf{p}(k_j, j, \psi) \cdot \mathbf{p}(k_{j+1}, j+1, \psi) \]

\[ P_{\psi}(k_j, k_{j+1}, \psi) \]
Product of the polarization terms
\[ = \mathbf{q}(k_j, j, \psi) \cdot \mathbf{q}(k_{j+1}, j+1, \psi) \]

\[ \mathbf{p}(k_j, j, \psi) \]
Polarization term of the azimuthal dependent part of mode \( k_j \) in region \( j \) for radial electric field component

\[ \mathbf{q}(k_j, j, \psi) \]
Polarization term of the azimuthal dependent part of mode \( k_j \) in region \( j \) for azimuthal electric field component

\[ VRI(k, j) \]
Input voltage reflection coefficient of mode \( k \) in region \( j \) (only valid for the first region)

\[ VRO(k, j) \]
Output voltage reflection coefficient of mode \( k \) in region \( j \) (only valid for the last region)

\[ x_{lower}, x_{upper} \]
Lower and upper limits of horizontal end points

\[ y(x) \text{ and } \tilde{y}(x) \text{ (lower and upper) } \]
Lower and upper limits of vertical end points

\[ Z(k, j) \]
Mode \( k \) region \( j \) wave impedance

\[ \Delta x \]
x-shift between waveguide centers at the junction

\[ \Delta y \]
y-shift between waveguide centers at the junction

\[ \Delta \theta \]
Angular rotation of the secondary axes relative to main frame axes performed after \( \Delta x \) and \( \Delta y \)

\[ \gamma(k, j) \]
Propagation constant of mode \( k \) region \( j \)
