LEAST SQUARES FOR FUZZY VECTOR DATA REGRESSION (U)

Aivas K. R. Celmink

We consider model fitting problems in which the mathematical model of an observed event is a system of equations involving model parameters and observables, and in which the data are fuzzy vectors. Such problems naturally arise in applications when data are scarce and information is vague about distributions of variances that are contained in the observations. Then it may only be possible to obtain estimates of membership functions of the data. A model can be fitted to such data by maximizing the membership values of the adjusted observations. We achieve this by minimizing the sum of squares of the deviations of the membership values from one.

The optimization problem simplifies significantly if the membership functions of the fuzzy vectors belong to a class of conical functions, which are defined in terms of an elliptic norm. Properties of these functions are discussed and a membership propagation formula derived which component-wise obeys the extension principle.
The least squares model fitting to the described fuzzy vector data deviates in important aspects from ordinary least squares. One obtains as a solution a fuzzy model parameter vector and a number of indicators which describe the quality of the fit, viz., the grade of compatibility between data and model, their discord and dilators of model and data membership functions. These new concepts are illustrated and discussed in the context of an example from a terminal ballistics problem.

1. INTRODUCTION

We consider model fitting problems in which the data are fuzzy vectors, and the mathematical model of the observed event is a system of equations involving observables and model parameters. Such problems naturally arise when data are scarce and information is not available about distributions of data inaccuracies. Then it may only be possible to obtain estimates of data scatter from past experience in the form of estimated data membership functions.

The fitting of the model consists of finding an optimal set of parameters and a corresponding set of corrections to the observations such that the model equations are satisfied. One obtains different solutions, depending on the definition of optimality. In this article, the optimally is defined in terms of a least squares objective function. Particularly, we shall maximizing the sum of squares of the deviations of the membership values of one. One obtains relatively simple algorithms for this problem if the membership functions of the data vectors belong to a particular class of functions. This class of conical functions is defined and discussed in Section 3, after a short exposition of general fuzzy model fitting problems in Section 2. The model fitting to fuzzy vectors with conical membership functions is described in Section 4, and Section 5 presents an application example.

An obvious extension of the problem to fuzzy models is mentioned in Section 2, and will be treated in a forthcoming paper.

2. FUZZIFICATION OF MODEL FITTING PROBLEMS

We define in this section a general least squares model fitting problem and outline several possibilities how the problem can be fuzzified.

Let \( X \in \mathbb{R}^n \) be the vector of all observations of an event, and let the mathematical model of the event be the equation

\[
F(X, t) = 0 \quad (2.1)
\]
where $F$ is a $s$-dimensional function, and $t$ is a $p$-dimensional model parameter. We assume that $F$ is twice differentiable with respect to all its arguments, and

$$n \geq s > p \geq 0$$

(2.2)

The goal of a model fitting operation is to find such a parameter vector $t$ that the model equation (2.1) is satisfied. Generally, this goal cannot be achieved, because the number $s$ of equations in (2.1) usually is larger than the number $p$ of free parameters. Then a solution of the problem only can be obtained by weakening the requirement that Eq. (2.1) be exactly satisfied. The replacement of Eq. (2.1) can be done in different ways and one obtains corresponding different solutions.

In usual least squares model fitting one assumes that the observations $X$ may contain errors and, therefore, the model equations should not be satisfied at $X$, but in the vicinity of $X$. That is, one corrects the observations $X$ by a term $c_X$ and replaces the model equations (2.1) by the constraint equations

$$F(X + c_X, t) = 0$$

(2.3)

One would like to have only small corrections and this is achieved by seeking such a solution $c_X$ and $t$ of Eq. (2.3) which minimizes the square of a norm of $c_X$. The problem may be formulated as follows:

$$\text{minimize } W = \| c_X \|^2$$
$$\text{subject to } F(X + c_X, t) = 0$$

(2.4)

Hence, a least squares model fitting problem is defined by the following set

$$\left\{ X ; \| c_X \| ; F ; W = \| c_X \|^2 \right\},$$

(2.5)

containing a data vector, a definition of a norm, a definition of a model function, and a definition of an objective function as the square of the norm of corrections.

The problem (2.5) can be fuzzified as follows. First, the data $X$ may be fuzzy. In this case one has in addition to the observed $X$ also a definition of its membership function $\mu_X$. Then we replace the definition (2.5) of the least squares model fitting problem by
\begin{align}
\left\{ \mathbf{x} ; \mu(\mathbf{c}) ; F ; W = (1-\mu(\mathbf{c}))^2 \right\}, \\
\text{or}
\begin{align}
\begin{aligned}
\text{minimize} & \quad W = (1-\mu(\mathbf{c}))^2 \\
\text{subject to} & \quad F(x+c, t) = 0.
\end{aligned}
\end{align}
\end{align}

This type of model fitting problems with fuzzy data is treated in Section 4.

Another possible fuzzification of the problem (2.5) is obtained by introducing a fuzzy model function. This can be done, for instance, by defining a set of functions with an associated membership function \( \mu_F \) \cite{1}. The data \( X \) then are assumed to be crisp, that is, one assumes \( c_X = 0 \). The corresponding least squares model fitting problem is defined by the set
\begin{align}
\left\{ \mathbf{x} ; \| c_X \| = 0 ; F ; \mu_F ; W = (1-\mu_F)^2 \right\},
\end{align}

or
\begin{align}
\begin{aligned}
\text{minimize} & \quad W = (1-\mu_F)^2 \\
\text{subject to} & \quad F(x, t) = 0.
\end{aligned}
\end{align}

Problems of this type are akin to a problem formulated by Tanaka et al. \cite{2}. We shall treat the problem (2.8) in a forthcoming paper.

Another kind of fuzzification is a combination of the former two, that is, one assumes that the data are fuzzy and use a fuzzy function to fit the data. It is probably the most useful case for applications.

Finally, one may fuzzify the objective function \( W \), for instance, by allowing to minimize other powers than the square of the norm or membership function. Because we restrict the present investigation to least squares minimization, we shall not further discuss this type of fuzzification.

3. FUZZY VECTOR SPACES AND SPREAD PROPAGATION FORMULAS

In many model fitting problems the data consist of a set of vectors rather than a set of scalars. Such data can be treated in the context of fuzzy sets by defining for each vector a membership function that depends on all
components of the vector. By choosing a proper class of membership functions one can simplify the numerical handling of the corresponding model fitting problem. We shall introduce and discuss in this section such a class of functions, namely a particular extension of the triangular membership function of a fuzzy scalar to $n$ dimensions.

Let $\tilde{a}$ be a fuzzy scalar. We associate with it the triangular membership function $\mu_{\tilde{a}}(x)$, defined by

$$
\mu_{\tilde{a}}(x) = \max \left\{ 0, 1 - \left| \frac{x-a}{s_a} \right| \right\}.
$$

We call $a$ the apex and $s_a$ the spread of $\tilde{a}$ and notice that $\mu_{\tilde{a}}(x)$ is completely determined by the two quantities $a$ and $s_a$. The spread may be considered as a measure for the accuracy of $\tilde{a}$. Then a reasonable dimensionless measure for the difference between a crisp point $x$ and the fuzzy observation $\tilde{a}$ is the norm

$$
\| x - \tilde{a} \|_a = \left| \frac{x - a}{s_a} \right|.
$$

The relation between this norm and the membership function of $\tilde{a}$ is

$$
\mu_{\tilde{a}}(X) = 1 - \min \left\{ 1, \left\| X - \tilde{a} \right\|_a \right\}.
$$

Now we extend this simple function to $n$ dimensions and demand that the extension, that is, the membership function $\mu_{\tilde{A}}(X)$ of a fuzzy vector $\tilde{A}$, has the following properties:

(A) Each component of $\tilde{A}$ has a triangular membership function, and

(B) the function $(1 - \mu_{\tilde{A}}(X))^2$ is differentiable in the domain where $\mu_{\tilde{A}}(X) > 0$.

The latter property is important for the simplification of the numerical treatment of model fitting problems.

A function with the properties (A) and (B) is the conical membership function

$$
\mu_{\tilde{A}}(X) = \max \left\{ 0, 1 - \left[ (X-A)\mathbf{T} P^{-1}_{A} (X-A) \right]^{1/2} \right\},
$$

where $P_A$ is diagonal matrix with diagonal elements which are the spread squares $s^2_{a_i}$ of the components $a_i$ of the vector $\tilde{A}$. Figure 1 shows $\mu_{\tilde{A}}(X)$ in the case $n = 2$. 
In analogy to Eq. (3.2) we also define a norm
\[ \|X - \tilde{A}\|_A = \left[ (X - A)^T P_A^{-1} (X - A) \right]^{1/2} \]  
and obtain an expression of the membership function in terms of the norm:
\[ \mu_A(X) = 1 - \min \left\{ 1, \|X - \tilde{A}\|_A \right\}. \]  
The boundary of the support of the membership function is given by the equation
\[ (X - A)^T P_A^{-1} (X - A) = 1. \]  
This boundary is a hyperellipsoid in the \( n \)-dimensional \( X \)-space. The principal axes of the ellipsoid are parallel to the coordinate axes, and their lengths are equal to \( 2s_{r_1} \). The matrix \( P_A \) which defines the membership function, we call the \textit{panderance matrix} of the fuzzy vector \( \tilde{A} \).

It is practical to slightly generalize the given definition of a conical membership function by permitting the support ellipsoid to have principal axes that are not parallel to the coordinate axes. Such a situation arises, e.g., if one chooses a different coordinate system. We determine the proper generalization of the definition by considering a linear coordinate transformation
\[ Z = DX + Z_0, \]  
The apex \( A \) of the fuzzy vector \( \tilde{A} \) with the panderance matrix \( P_A \) is mapped by this transformation into a vector
\[ B = DA + Z_0, \]  
and the panderance matrix \( P_B \) of \( \tilde{B} \) is obtained by the following spread propagation formula:
\[ P_B = DP_A D^T. \]  
We first verify this formula for the case where (3.8) is a regular coordinate transformation, that is, \( D \) is a non-singular \( (n \times n) \)-matrix. Then \( P_B \), computed by Eq. (3.10), is positive definite and the membership function
\[ \mu_B(Z) = 1 - \min \left\{ 1, \left[ (Z - B)^T P_B^{-1} (Z - B) \right]^{1/2} \right\}. \]  
has the property
\[ \mu_B(Z(X)) = \mu_A(X), \]  
\[ (3.12) \]
because

$$(Z-B)^T \mathcal{P}_B^{-1}(Z-B) = (X-A)^T D(D^T)^{-1} \mathcal{P}_A^{-1} D^{-1} D(X-A) = (X-A)^T \mathcal{P}_A^{-1}(X-A).$$ (3.13)

In the Z-coordinate system, each component again has a triangular membership function, the projection of the cone defined by the panderance matrix $P_B$. The spread $s_{bi}$ of each component $b_i$ of $B$ equals the square root of the $i$-th diagonal element of $P_B$. The support ellipsoid's principal axes are in general not parallel to the axes of the Z-coordinate system.

One sees from the formula (3.10) that the panderance matrix of a conical membership function merely has to be positive definite. However, as we shall see later, degenerated support ellipsoids do occur. Therefore we shall assume that the panderance matrix only is positive semidefinite.

The elements of a panderance matrix $P_A$ have, in general, different physical dimensions, corresponding to the dimensions of the components of $\hat{A}$. They also may have different orders of magnitude, depending on the units which are used to express $A$. Therefore, a more lucid representation of $P_A$ is in terms of the spreads $s_{ai}$ of the components $\hat{a}_i$ of $\hat{A}$ and a concordance matrix $C_A$, which is related to $P_A$ by the formula

$$P_A = S_A C_A S_A^T,$$

or

$$C_A = S_A^{-1} P_A S_A^{-1}.$$ (3.14)

where $S_A$ is a diagonal matrix with spreads $s_{ai}$ in the diagonal. Elementwise the relation (3.14) between panderances, concordances and spreads is

$$P_{aij} = C_{aij} s_{ai} s_{aj}, \quad i, j = 1, \ldots, n.$$ (3.15)

The concordance matrix has dimensionless elements, less or equal one in absolute value, with ones in the diagonal.

So far we only have verified the spread propagation formula (3.10) for regular linear coordinate transformations. It is, however, also valid for any other linear function (3.8) in the sense that the membership function which is produced by Eq. (3.10) for each component of $Z$ satisfies the extension principle. Now we shall prove this property of the formula.

Let one component of the linear function (3.8) be

$$z = d^T x + z_0.$$ (3.16)
The fuzzy vector $\tilde{A}$ is mapped into a fuzzy number $\tilde{b}$ with the apex

$$b = d^TA + z_0 .$$  \hspace{1cm} (3.17)

The pandereance (the spread square) of $\tilde{b}$ is according to (3.10)

$$s_b^2 = d^TP_A d$$  \hspace{1cm} (3.18)

and the membership function of $\tilde{b}$ is

$$\mu_b(z) = 1 - \min (1, |z-b|/s_b) .$$  \hspace{1cm} (3.19)

According to the extension principle, the membership function of should be

$$\mu_b(z) = \max_{x: d^Tx + z_0 = z} \mu_A(x) .$$  \hspace{1cm} (3.20)

We shall show that $\mu_b(z)$, computed from (3.20), equals the $\mu_b$ computed with the formula (3.19). To that end, we reformulate the right hand side of Eq. (3.20) as the following constrained minimization problem:

$$\begin{align*}
\text{minimize} & \quad \|X-\tilde{A}\|_A^2 = (X-A)^T \overline{P_A}^{-1} (X-A) \\
\text{subject to} & \quad d^T(X-A) = z-b .
\end{align*}$$  \hspace{1cm} (3.21)

We use a Lagrange multiplier $k$ and obtain the following normal equations of the problem (3.21):

$$\begin{align*}
\overline{P_A}^{-1} (X-A) - kd & = 0 , \\
d^T(X-A) & = z-b .
\end{align*}$$  \hspace{1cm} (3.22)

We solve the first equation (3.22) for $k$, obtaining

$$k = d^T(X-A)/(d^TP_A d)$$

or

$$k = (z-b)/(d^TP_A d) .$$  \hspace{1cm} (3.23)

Substituting this into the first equation (3.22) and multiplying from the left by $(X-A)^T$ one obtains

$$\|X-\tilde{A}\|_{A \min}^2 = (z-b)^2/(d^TP_A d)$$  \hspace{1cm} (3.24)

or

$$\|X-\tilde{A}\|_{A \min} = |z-b|/s_b .$$  \hspace{1cm} (3.25)
Therefore,

\[
\max \mu_A(X) = 1 - \min \left\{ 1, \frac{1}{\min_{1 \leq i \leq n} \|x_i - \tilde{A}_i\|} \right\} = 1 - \min \left\{ 1, \frac{|z - b|}{s_b} \right\}, \tag{3.26}
\]

that is, the solution of (3.20) is (3.19).

The proof can be modified to cover also singular cases with semidefinite panderance matrices \(P_A\) by restricting the minimization (3.21) to the subspace where \(P_A\) is definite. Hence, we have shown that the spread propagation formula (3.10) componentwise satisfies the extension principle for any linear function of \(X\). If the function \(Z(X)\) is not linear, then one may obtain an approximate panderance matrix \(P_B\) for \(B = Z(A)\) by linearizing the function. Then the propagation formula is

\[
P_B = \frac{\partial Z}{\partial X} P_A \left( \frac{\partial Z}{\partial X} \right)^T, \tag{3.27}
\]

where \(\partial Z/\partial X\) is the Jacobian matrix of the function \(Z(X)\). The quality of the approximation depends on the size of the second order derivatives of \(Z(X)\), relative to the panderances and to the first order derivatives.

So far we only have considered single fuzzy vectors and defined a norm for the distance between a fuzzy and a crisp vector. The membership function was expressed by Eq. (3.6) in terms of this distance. We shall also need a measure for the distance between two fuzzy vectors. Now we give the necessary definitions and take for simplicity a general approach.

Let \(H_n\) be a vector space with fuzzy \(n\)-component vectors as elements. We assume that each \(\tilde{A} \in H_n\) is assigned a metric which defines a distance \(h(X, \tilde{A})\) in \(R^n\), that is, between any \(X \in R^n\) and \(\tilde{A} \in H_n\). We also assume that the membership function \(\mu_{A(X)}\) of \(\tilde{A}\) is related to \(h(X, \tilde{A})\) by the formula

\[
\mu_{A(X)} = \max \left\{ 0, 1 - h(X, \tilde{A}) \right\} = 1 - \min \left\{ 1, h(X, \tilde{A}) \right\}. \tag{3.28}
\]

The distances \(h(X, \tilde{A})\) are not useful for the measurement of distances in \(H_n\) because in general \(h(\tilde{A}, B) \neq h(\tilde{B}, A)\). We therefore, define a discord between two elements of \(H_n\) by the formula

\[
D(\tilde{A}, \tilde{B}) = \min_X \max \left\{ h(X, \tilde{A}), h(X, \tilde{B}) \right\} \tag{3.29}
\]

\(D\) is symmetric but it is not a distance in \(H_n\). That is, it has the properties...
and
\[ D(\tilde{A}, \tilde{B}) > 0 \text{ if } A \neq B \]
\[ D(\tilde{A}, \tilde{B}) = 0 \text{ if } A = B \] (3.30)

but it does not satisfy the triangle inequality.

As a complement to the discord \( D(\tilde{A}, \tilde{B}) \) we also define a grade of collocation of two fuzzy vectors \( \tilde{A} \) and \( \tilde{B} \) by
\[
\gamma(\tilde{A}, \tilde{B}) = \max_{X \in \mathbb{R}_n} \min \left\{ \frac{\mu_A(X) \cdot \mu_B(X)}{\mu_A(X) + \mu_B(X)}, 1 \right\}.
\]
(3.31)

Because we have assumed the relation (3.28) between \( \mu_A \) and \( h(X, \tilde{A}) \), we also can express the grade of collocation in terms of the discord:
\[
\gamma(\tilde{A}, \tilde{B}) = \max \left\{ 0, 1-D(\tilde{A}, \tilde{B}) \right\} = 1 - \min \left\{ 1, D(\tilde{A}, \tilde{B}) \right\}.
\] (3.32)

In the special case of vectors with conical membership functions we define \( h(X, \tilde{A}) = ||X - \tilde{A}|| \). In this case, the distance \( h(X, \tilde{A}) \) is inversely proportional to the spreads of the components of \( A \). If one multiplies the spreads of \( \tilde{B} \) by a factor \( \phi \) and lets \( \phi \) approach zero, then one obtains for the discord the limit
\[
\lim_{\phi \to 0} D(\tilde{B}, \tilde{A}) = h(B, \tilde{A}).
\] (3.33)

The limit of a membership function with vanishing support may be considered as the membership function of a crisp vector. In this sense, the discord \( D(\tilde{B}, \tilde{A}) \) approaches the distance \( h(B, \tilde{A}) \) between a crisp vector and \( \tilde{A} \), as \( \tilde{B} \) becomes a crisp \( B \). Hence the discord is a convenient generalization of the distance in \( \mathbb{R}_n \) with a proper limit property.
A general formulation of a least squares model fitting problem with fuzzy data was given in Section 2 by Eq. (2.7). Now we shall give a slightly different formulation which is more adequate for the present discussions.

Let the observations be fuzzy vectors \( \tilde{X}_i, i=1, \ldots, s \), each having the dimension \( n_i \), and a membership function \( \mu_{\tilde{X}_i} \), represented by a panderance matrix \( P_i \). Let the model of the event be defined by the equations

\[
F_i(X_i + \mathbf{c}_i, t) = 0, \quad i = 1, \ldots, s, \tag{4.1}
\]

where \( t \) is a \( p \)-dimensional model parameter and \( F_i \) are \( r_i \)-dimensional functions. We assume that the dimensions \( n_i, r_i, \) and \( p \) satisfy the conditions

\[
\sum_{i=1}^{s} n_i \geq \sum_{i=1}^{s} r_i > p \geq 0. \tag{4.2}
\]

Compared to the formulation in Section 2 we now have assumed that the model equations have subsets which depend on distinct subsets of the observations. (The present formulation includes the formulation of Section 2 as the special case \( s=1 \). Such a partitioning is not always possible, but it offers substantial algorithmic advantages.) Also, many model fitting problems are naturally formulated by partitioned equations (4.1), e.g., in standard least squares problems where the \( F_i \) are scalar functions and all \( X_i \) are distinct.

A least squares model fitting problem now may be formulated as follows:

\[
\begin{aligned}
\text{minimize} & \quad W = \sum_{i=1}^{s} \left[ 1 - \mu_{\tilde{X}_i}(X_i + \mathbf{c}_i) \right]^2, \\
\text{subject to} & \quad F_i(X_i + \mathbf{c}_i , t) = 0, \quad i = 1, \ldots, s,
\end{aligned} \tag{4.3}
\]

where

\[
\mu_{\tilde{X}_i}(X_i + \mathbf{c}_i) = 1 - \min \left\{ 1, \left( \mathbf{c}_i^T P_i^{-1} \mathbf{c}_i \right)^{1/2} \right\}. \tag{4.4}
\]
We recall the definition (3.5) of a norm

$$\|c_i\|_{X_i} = (c_i^T P_i^{-1} c_i)^{1/2}$$ (4.5)

and observe that the corrected observation $X_i+c_i$ only is meaningful if the correction $c_i$ satisfies the inequality $\|c_i\|_{X_i} < 1$. If $\|c_i\|_{X_i} \geq 1$ then the membership function $\mu_{X_i}(X_i+c_i)$ vanishes and in general the function $F_i(X_i+c_i,t)$ might not even be defined. Therefore, one should supplement the constraints of the minimization problem with the conditions $\|c_i\|_{X_i} < 1$ with $\gamma$ satisfying $0 < \gamma < 1$.

We also express the objective function in terms of the $\|c_i\|_{X_i}^2$ using the relation (4.4). The advantage of this reformulation is that the new objective function is differentiable with respect to the $c_i$ for all finite $c_i$. As a result one can use Lagrange multiplier techniques for the numerical solution of the problem. The restriction to conical membership functions was made in order to have such a differentiable objective function. Using the new objective function and the above discussed additional constraints one obtains the following constrained minimization problem:

\[
\begin{align*}
\text{minimize} & \quad W = \sum_{i=1}^{s} c_i^T P_i^{-1} c_i, \\
\text{subject to} & \quad F_i(X_i+c_i,t) = 0, \quad i = 1, \ldots, s \\
\text{and} & \quad \|c_i\|_{X_i} < 1 - \gamma, \quad i = 1, \ldots, s.
\end{align*}
\] (4.6, 4.7)

One observes that the formal difference between an ordinary least squares problem and a model fitting with fuzzy data are the constraints (4.7). Conceptually, these constraints are compatibility conditions between data and model, and they identify outliers. Geometrically, they require that for all $i = 1, \ldots, s$ the
support of the function \(\mu_{X_i}(X) - \gamma\) intersects with the fitted surface \(F_i(X, t) = 0\). However, the results of the fitting is not a crisp function, but a fuzzy set of functions, because it has been computed from fuzzy data. Therefore, the fitted surface also is fuzzy. In the \(X\)-space it has a membership function \(\mu_{F_i}(X)\), which equals one on the surface \(F_i = 0\), and has a finite support around that surface. The condition (4.7) means that the support of the functions \(\mu_{X_i}(X) - \gamma\) and \(\mu_{F_i}(X) - \gamma\) are required to intersect. It is more reasonable to only require that the supports of \(\mu_{X_i}(X) - \gamma\) and \(\mu_{F_i}(X) - \gamma\) intersect. Now we shall formulate a condition based on this requirement, and replace (4.7) by this condition.

First, we compute the membership function of the fitted function \(F_i\). Let \(P_t\) be the pandence matrix of the fuzzy model parameter vector \(t\). (One obtains an estimate of \(P_t\) concurrently with the numerical solution of the minimization problem (4.6), see Ref 3). The pandence \(P_{F_i}\) of \(F_i\) is approximately given by Eq. (3.27), that is, by

\[
P_{F_i} = F_{t_i} P_t F_{t_i}^T ,
\]

where \(F_{t_i} = \delta F_i / \delta t\). We assume that the \(r_i\) components of \(F_i\) are independent functions of \(t\) and that \(r_i \leq p\), so that the rank of \(F_{t_i}\) equals \(r_i\). Then \(P_{F_i}\) is positive definite, and defines the following norm for \(F_i\):

\[
\|F_i(X)\|_{F_i} = (F_{t_i}^T P_{F_i}^{-1} F_{t_i})^{1/2} ,
\]

and the corresponding membership function in the \(X\)-space

\[
\mu_{F_i}(X) = 1 - \min \left\{ 1 , \|F_i(X)\|_{F_i} \right\} .
\]

Next, we define the grade of compatibility between the observation \(\hat{X}_i\) and the fitted model by

\[
\gamma_{X_{Fi}} = \max_{X \in R_{ni}} \min \left\{ \mu_1(X) , \mu_{F_i}(X) \right\} .
\]

The constraint (4.7) of the minimization problem (4.6) should be replaced by the requirement that the grade of compatibility is for each observation higher than \(\gamma\), that is, by

\[
\gamma_{X_{Fi}} > \gamma , \quad i = 1, \ldots, s .
\]
In this form the constraints may not be easily implemented, but in most cases one can approximate them by conditions on the grade of collocation, Eq. (3.31), between the observations $\tilde{X}_i$ and the corrected observations $\tilde{X}_i + \hat{c}_i$. Using Eq. (3.32) we shall express these conditions in terms of the discord between these two vectors. We use $||\epsilon_i||_{\tilde{X}_i}$ as a distance measure $h(X_i + \epsilon_i, \tilde{X}_i)$ from $\tilde{X}_i$ and a linearized form of $||F_i||_{F_i}$ as a distance measure $h(X, \tilde{X}_i + \hat{c}_i)$ from $\tilde{X}_i + \hat{c}_i$. Now we shall derive this linearized form. Let $V_0$ be a point on the surface $F_i = 0$. Then to the first order

$$\Delta F_i = F_i(X_0 + b, t) - F_i(X_0, t) = F_i(X_0 + b, t) = F_{xi} b$$  \hspace{1cm} (4.13)$$

where $F_{xi} = \partial F_i(X_0, t) / \partial X$. Substituting this expression for $F_i$ into Eq. (4.9) one obtains

$$||\Delta F_i|| = (b^T F_{xi}^T F_{xi}^{-1} b)^{1/2}$$  \hspace{1cm} (4.14)$$

Let

$$F_{xi}^{-1} = F_{xi}^T F_{xi}^{-1} F_{xi} b$$  \hspace{1cm} (4.15)$$

$F_{xi}^{-1}$ is a $n_i \times n_i$-matrix and, because in general $n_i > r_i$ (unless the model is a point) the matrix is only semidefinite. Therefore, the surfaces $b^T P_i b = \text{const}$ are degenerated ellipsoids in the $X$-space, namely, cylinders with rulings that are parallel to $F_i = 0$. The pseudonorm $||b||_{F_i} = (b^T P_i b)^{1/2}$ only measures that component of $b$ which is orthogonal to $F_i = 0$. (Orthogonal in the sense of the inner product associated with the pseudonorm). The use of the linearized pseudonorm $||b||_{F_i}$ instead of $||\Delta F_i||_{F_i}$ in the definition (4.10) of the membership function $\mu_{F_i}$ amounts to a linearization of $\mu_{F_i}$ in the $X$-space. Now we use $||b||_{F_i}$ as a measure for the distance in $X$-space from the corrected observation, that is,

$$h(X_i + \epsilon_i + b, \tilde{X}_i + \hat{c}_i) = ||b||_{F_i}$$  \hspace{1cm} (4.16)$$

With these definitions, the discord between $\tilde{X}_i$ and $\tilde{X}_i + \hat{c}_i$ is according to Eq. (3.29)

$$D_i = \min_{X \in R_{ni}} \max \left\{ ||\epsilon||_{X_i}, ||b||_{F_i} \right\}$$  \hspace{1cm} (4.17)$$

13
where \( c = X - X_i \) and \( b = X - (X_i + c_i) \)

If the linearization (4.14) is sufficiently accurate and the dimension of \( F_i \) equals one then the value of the discord \( D_i \) can be explicitly calculated from the two norms of the residual \( ||c_i||_{\chi i} \) and \( ||c_i||_{F_i} \), because the minimum in Eq. (4.17) is attained at a point on the straight line segment between \( X_i \) and \( X_i \) and \( c_i \). We demonstrate this property of the minimum by observing that \( c_{\chi i} \) is a convex function and showing that the level planes \( b_{F_i} = \text{const} \) are tangential to the level surfaces of \( c_{\chi i} = \text{const} \) for all points of the segment. A plane \( b_{F_i} = \text{const} \) is spanned by vectors \( q \) which satisfy the equation

\[
F_{x_i} q = 0 \tag{4.18}
\]

(See the definition Eq. (4.14).) A plane through the point \( X_i + c \) and tangential to \( ||c||_{\chi i} = \text{const} \) is spanned by vectors \( q \) which satisfy the equation

\[
c^T P_i^{-1} q = 0 \tag{4.19}
\]

(See the definition Eq. (4.5)). Let \( X_i + c \) be on the straight line through \( X_i \) and \( X_i + c_i \), i.e., \( c = \alpha c_i \). The residual is a solution of the least squares problem (4.6). Therefore, it satisfies the following equation from Reference 4.

\[
c_i = P_i F_{x_i}^T (F_{x_i} P_i F_{x_i}^T)^{-1} F_{x_i} c_i \tag{4.20}
\]

Substituting \( \alpha \) times the right hand side of Eq. (4.20) for \( c \) in Eq. (4.19), one obtains

\[
c_i^T F_{x_i}^T (F_{x_i} P_i F_{x_i}^T)^{-1} F_{x_i} q = 0 \tag{4.21}
\]

The set of all vectors \( q \) satisfying Eq. (4.21) are in the plane tangential to \( ||c||_{\chi i} = \text{const} \). Because \( q \) satisfies Eq. (4.18), it also satisfies Eq. (4.21) and, therefore, a tangent vector. Hence \( ||b||_{F_i} = \text{const} \) is tangential to \( ||c||_{\chi i} = \text{const} \).

Now we compute the discord \( D_i \), taking in Eq. (4.17) the maximum only over points of the straight line between \( X_i \) and \( X_i + c_i \). On that line, \( c = \alpha c_i \) and \( b = (\alpha - 1)c_i \). Therefore, Eq. (4.17) becomes
\[ D_i = \min_a \max \left\{ |a| \left\| c_i \right\|_{X_i} , |1-a| \left\| c_i \right\|_{F_i} \right\} \]  
(4.22)

which has the solution

\[ D_i = \left\| c_i \right\|_{X_i} \left\| c_i \right\|_{F_i} / \left( \left\| c_i \right\|_{X_i} + \left\| c_i \right\|_{F_i} \right). \]  
(4.23)

The corresponding grade of collocation between \( X_i \) and \( X_i + c_i \) is

\[ \gamma_i = \max \left\{ 0, 1-D_i \right\}. \]  
(4.24)

We use this \( \gamma_i \) as an approximation to \( \gamma_{\lambda F_i} \) and replace the compatibility condition (4.12) by

\[ \gamma_i > \gamma, \quad i = 1, \ldots, s. \]  
(4.25)

With the same approximation we define the overall discord between data and model as

\[ D = \max_{i=1,\ldots,s} D_i, \]  
(4.26)

and the overall grade of compatibility as

\[ \gamma = \min_i \gamma_i = \max \left\{ 0, 1-D \right\}. \]  
(4.27)

The reformulated least squares model fitting problem (4.6) and (4.7) is:

\[
\begin{align*}
\text{minimize} & \quad W = \sum_{i=1}^{s} c_i^T P_i^{-1} c_i \\
\text{subject to} & \quad F_i(X_i + c_i, t) = 0, \; i = 1, 2, \ldots, s \\
& \quad \left\| c_i \right\|_{X_i} \left\| c_i \right\|_{F_i} / \left( \left\| c_i \right\|_{X_i} + \left\| c_i \right\|_{F_i} \right) < 1 - \gamma.
\end{align*}
\]  
(4.28)

The numerical solution of the model fitting problem may be obtained by first solving Eq. (4.28), and checking the conditions (4.29) after solution. If the conditions are satisfied, then one has the solution. If for some \( \hat{X}_i \), the compatibility grade is less than the required \( \gamma_i \), then one may take several actions. First one should recheck the data and depending on the circumstances, one
may discard outliers, lower the required compatibility grade $\gamma$, modify the spread estimates of observations and/or model, change the model, or try to find a solution that does satisfy Eq. (4.29). The latter means, however, an accommodation of outliers at the expense of the overall fit. A solution will not always exist and, if it does exist, it usually will not be desirable. Discarding of observations and changing the model equations are problem dependent actions and will not be discussed here. Changing of $\gamma$ merely changes the right hand side of Eq. (4.29). The more general actions are the modifications of the spread estimates which we now shall discuss.

We first consider the effect of changing all spread estimates of the observations $X_i$ by a factor $\phi_X$. Then all panderance matrices $P_i$ are multiplied by $\phi_X$ and $||e_i||_{P_i}$ as well $||e_i||_{P_i}$ are multiplied by $1/\phi_X$. ($P_i$ in Eq. (4.8) receives the factor $\phi_X$, which affects $||b||_{P_i}$ through Eq. (4.14)). Consequently, the discords $D_i$ in Eq. (4.23) are multiplied by $1/\phi_X$, too. Hence in order to make all discords less than $1 - \gamma$, i.e., all compatibility grades larger than $\gamma$, one may multiply the estimated data spreads by

$$\phi_X = \max_i \left\{ D_i/(1 - \gamma) \right\}. \tag{4.30}$$

We call $\phi_X$ the data spread dilator. If the conditions (4.29) are satisfied, then the data spread dilator is less or equal one. If the compatibility grade $\gamma$ between data and model is less than $\gamma$, then the data spread dilator $\phi_X$ provides a measure for the seriousness of maximum deviation from $\gamma$. The individual $\phi_X$, i.e., the right hand side terms of Eq. (4.30), provide such a measure for each observation $X_i$.

Now we consider model spread dilators. One may use such a dilator if the compatibility grade $\gamma$ between data and model is less than the desired $\gamma$, but the data spread estimates and the model equations are firmly established. Then one may achieve the desired grade of compatibility by increasing the computed fuzziness of the model, i.e., by dilating the spread of the model. In general, this can be done by modeling the spreads of the model function concurrently with the modeling of the event. We consider here the simplest case of such a modeling, namely the multiplication of the panderance matrix $P_i$ in Eq. (4.8) by a factor. A value of the factor may be obtained from one of the following two requirements. First, one obtains a minimal model spread dilator $\phi_F$ by the requirement that the constraints (4.29) be satisfied. This dilator is a complement to the data spread dilator $\phi_X$. We obtain its value by observing that the multiplication of the model parameter spreads by $\phi_F$ changes $||e_i||_{P_i}$ in Eq. (4.29) by the factor $1/\phi_F$, and leaves the $||e_i||_{N_i}$ unchanged. Then all
constraints (4.29) can be satisfied if $\phi_F$ has the value.

$$\phi_F = \max_i \max \left\{ 0, \|c_i\|_{F_i} / (1 - \gamma) - \|c_i\|_{\hat{F}_i} / \|c_i\|_{X_i} \right\}. \quad (4.31)$$

$\phi_F$ is less or equal one if all $D_i < 1 - \gamma$, i.e., if the original model is compatible with the data to the desired grade. Otherwise $\phi_F$ has a value bigger than one. The individual $\phi_{Fi}$, i.e., the terms on the right hand side of Eq. (4.31) again provide a measure of the seriousness of the incompatibility between the observation $\hat{X}_i$ and the fitted model. If the support of the function $\mu_{X_i - \gamma}$ intersects with the surface $F_i = 0$ then $\phi_{Fi}$ equals zero.

Another model spread dilator is more practical for application. We call it the *inclusive model spread dilator* $\Phi_F$ and determine its value from the requirement that the support of $\mu_{X_i - \gamma}$ should include all support ellipsoids of the functions $\mu_{Fi - \gamma}$. We obtain an approximate value of $\Phi_F$ by the following algorithm. First, we find for each observation $\hat{X}_i$, that point on the straight line through $X_i$ and $X_i + c_i$ which has the membership value $\gamma$ and which is on the side of $X_i$ opposite to $X_i + c_i$. That point has the coordinates

$$Y_i = X_i + c_i (1 - \gamma) / \|c_i\|_{X_i}. \quad (4.32)$$

The membership value of $F_i$ at that point is

$$\mu_{Fi}(Y_i) = 1 - \min \left\{ 1, \|F_i(Y_i)\|_{F_i} \right\}, \quad (4.33)$$

where

$$\|F_i(Y_i)\|_{F_i} = \left( F_i(Y_i)^T P_{Fi}^{-1} F_i(Y_i) \right)^{1/2}$$

is calculated by Eq. (4.9). We want this value to be equal or larger than $\gamma$. Therefore,
the spread of the model parameter vector should be multiplied by

\[ \Phi_{Fi} = \| F_i(Y_i) \|_{Fi} / (1 - \gamma) \]  

(4.34)

The overall inclusive model spread dilator is

\[ \Phi_F = \max_i \Phi_{Fi} \]  

(4.35)

In summary, we have introduced the following indicators which measure the quality of the model fitting:

- D - discord between data and model,
- \( \gamma \) - grade of compatibility between data and model,
- \( \phi_X \) - data spread dilator,
- \( \phi_F \) - minimal model spread dilator,
- \( \Phi_F \) - inclusive model spread dilator.

The last three indicators depend on a desired minimum grade of compatibility, whereas the first two indicators are independent of such a grade.

5. EXAMPLE

As an example of a model with fuzzy experimental data we present the following treatment of perforation of a plate by projectiles. In perforation experiments, one is interested in the minimum striking velocity which is needed to achieve perforation. That velocity is called the ballistic limit velocity and for a given target it depends on the materials of the projectile and target, on the form of the projectile, and on the obliquity of the impact. The limit velocity typically is determined by firing projectiles with different velocities and
observing their residual velocities (the velocity after penetration). The limit velocity is computed from these data by one of several available methods which all amount to some kind of interpolations between zero and non-zero residual velocities. The result contains observational errors as well as intrinsic variations of the limit velocity between rounds due to unknown causes, e.g., due to variations of target and projectile material properties. (Such variations manifest themselves e.g., by overlapping regions of zero and non-zero residual velocities.) The number of experiments usually is too small to determine a distribution of the result, but expert estimates of possible variations are available from past experience. Table I contains a set of observed limit velocities. (The data are taken from Ref. 5). The targets were identical in all cases. The projectiles were cylindrical rods with different nose shapes, quantitated in the table by a "shape quotient" which is the ratio of nose length to rod length. Because it is not certain that this ratio adequately describes the significance of the projectile's geometry, a substantial spread of 0.05 was assigned to the value of the ratio. The spread of the limit velocity was estimated from past experience to be about 50 m/s. However, in two cases the actual observations were not sufficient to guarantee such an accuracy, and, therefore, corresponding larger spreads were assumed in these cases.

The projectiles were fired in two modes: normal to the target plate, and at a constant angle of obliquity. The purpose of the experiments was to determine whether and how the shape of the projectile affects the limit velocity. The problem was handled by fitting a constant and a linear function to the two series of observed limit velocities, and by comparing the results. The numerical fitting of the fuzzy data was done with the general least squares computer program COLSAC [6].

The data are in the present case two-component fuzzy vectors \((\tilde{Q}, \tilde{V})\). The component \(\tilde{Q}\) is the dimensionless shape quotient and the component \(\tilde{V}\) is the corresponding limit velocity in m/s. The models of the limit velocity were the linear functions

\[
V = a + bQ .
\]  \hspace{1cm} (5.1)

Using the technique described in Section 4, one obtains as a result of each model fitting a fuzzy parameter vector with the components \(\tilde{a}\) (m/s) and \(\tilde{b}\) (m/s), and a corresponding \((2 \times 2)\) panderance matrix. In case of a constant model one sets \(b=0\) in Eq. (5.1) (\(\tilde{b}\) is a crisp zero in that case), and the model fitting algorithm provides only \(\tilde{a}\) and its panderance. In the \((a, b)\)-space, the special solution vector \((\tilde{a}, 0)\) with a crisp second component has a singular
panderance matrix. The support of the corresponding membership function is a segment of the a-axis. The numerical values of the four fuzzy parameter vectors are listed in Table II. The data and the fitted curves are shown in Figures 2 through 7.

Next, we discuss and illustrate the various measures of compatibility between data and models. Table II lists these indicators for each data set \((\dot{Q}, \dot{V})\) from the normal impact observations series. (See also Figures 2 and 4). To be specific we have assumed that the desired grade of compatibility is \(\gamma = 0.3\), and Table III shows that the normal impact data exceed this level of compatibility with the constant model as well as with the linear model. Consequently the data dilators and the minimal model dilators all are less than one.

Figure 2 shows the normal impact data and the fitted constant model. Each data point is plotted with the support ellipse of its membership function. A dotted ellipse indicates the level line \(\mu_X = 0.3\). The fitted velocity model is the line \(\dot{V} = -819.2\) m/s. It is a fuzzy line, with a spread of 24.5 m/s, as indicated in Figure 2. The dotted horizontal lines are the level lines \(\mu_X = 0.3\). The data dilators and the minimal model dilators all are less than one (see Table III). Because the supports of \(\mu_{X} - 0.3\) and \(\mu_{F} - 0.3\) intersect, the inclusive model dilators in Table III for the desired grade of compatibility \(\gamma = 0.3\) are larger than one. Similarly, the supports of \(\mu_{X}\) are not subsets of the support of \(\mu_{F}\), and therefore, also the inclusive model dilators for \(\gamma = 0\) ought to be larger than one. Their maximum value \(\Phi_0 = 6.832\) is listed in Table II. If the spread of the model is dilated by the factors \(\Phi_0\) or \(\Phi_{0.3}\), then it includes the supports of the data up to the corresponding level 0.0 or 0.3, respectively.

Figure 3 shows the same data as Figure 2 but the fitted model is a linear function. The discords between data and fitted model are smaller than for the constant model (see Table III). The inclusive model dilators have reasonable values, \(\Phi_0 = 2.290\) for \(\gamma = 0.0\) and \(\Phi_{0.3} = 2.407\) for \(\gamma = 0.3\). Figure 4 shows the effect of these dilators. It displays the same data and model as Figure 3, but the model spread has been dilated. The solid line indicates the boundary of the support of \(\mu_{F}\), if the dilator \(\Phi_0 = 2.290\) is used. The dotted lines indicate the boundary of the support of \(\mu_{F}\) and the level line \(\mu_{F} = 0.3\) if the dilator \(\Phi_{0.3} = 2.407\) is used. In the former case, the support of \(\mu_{F}\) includes all supports of the data. In the second case, the support of \(\mu_{F} - 0.3\) includes the supports of \(\mu_{X} - 0.3\). Figure 4 confirms that the approximately calculated dilators by Eq. (4.34) are sufficiently accurate in this example.

Next, we consider the oblique impact data listed in Table IV. The table indicates that the data are incompatible with a constant limit velocity model. and Figure 5 shows that the supports of the data indeed do not intersect with 20.
the support of the fitted model, except for one data point. All dilators are larger than one, particularly the inclusive model dilators \( \Phi_0 = 11.579 \) and \( \Phi_{0.3} = 14.941 \). (Table II).

Figure 6 shows the result of fitting a linear function to the oblique impact data. The data set is compatible with the model, the grade of compatibility is 0.298. Consequently, all data dilators and minimal model dilators for the desired grade of compatibility \( \gamma = 0.3 \) are less than one or close to one (Table IV). The inclusive model dilators are somewhat large, \( \Phi_0 = 4.625 \) and \( \Phi_{0.3} = 5.464 \). Using these dilators to increase the spread of the fitted function one obtains the result shown in Figure 7. As in Figure 4, we have plotted as solid curves the level lines \( \mu_F = 0 \), dilated by \( \Phi_0 \). For the spread of the fitted function, dilated by \( \Phi_{0.3} \) we have plotted as dotted curves the level lines \( \mu_F = 0.0 \) and \( \mu_F = 0.3 \). The regions between these curves should include all corresponding supports of the data membership functions. One notices a slight intersection of the boundary curves of the second data point (\( Q = 0.052 \)) with the model spread boundaries. This intersection (instead of a tangent) is caused by the approximate calculation of the dilators by Eq. (4.34), only using function values along the line through the observation \( X \) and the corrected observation \( X + \epsilon \).

One can conclude from the presented results that in case of oblique impact the limit velocity indeed depends on the nose shape, increasing with the slenderness of the projectile’s nose. In the normal impact case there seems to be a slight decrease of the limit velocity with increasing nose shape quotient. The data are compatible with the constant model to a grade 0.640 and compatible with the linear model and a grade 0.859. The increase of the compatibility is not very large and one might ask to what degree both fitted models differ from each other. A measure for this difference is the grade of collocation between the two fuzzy model parameter vectors which define the models (Table II). Figure 8 shows the two vectors with the corresponding supports of their membership functions in the parameter space. As mentioned before, the support of the parameter \( (a, 0) \), i.e., the constant model parameter, consists of a segment of the \( a \)-axis. The support of the linear model parameter membership function is an ellipse, shown in Figure 8 with a solid line. The dotted line curve in the figure is the level line \( \mu = 0.3 \). The grade of collocation between these two vectors turns out to be 0.080. If one increases the spread of the parameters by the factors \( \Phi_0 \) or \( \Phi_{0.3} \), then one also increases the grade of collocation, namely to 0.598 and 0.618, respectively.

For the oblique impact data the model vectors of constant and linear models have a zero grade of collocation. Figure 9 shows the situation of the vectors in the parameter space. The discord between the vectors is in this case
3.250. (If one uses the dilators $\Phi_0$ or $\Phi_{0.3}$, then the grades of collocation are 0.296 and 0.404, respectively.) The large discord is an indication that there is a significant difference between both models. In such a situation one should use the better model to represent the data, in this case the linear model. This leads to the same conclusion as above: for oblique impact, the limit velocity does increase with the slenderness of the projectile.

We make a final comment to the representation of the data by a model, and consider as an example the oblique impact data. A straightforward determination of the model produces the result, shown in Figure 6, which is compatible with the data, but does not include all supports of the data. Using model dilators one obtains the results shown in Figure 7, which includes all data supports, but seems to be excessively pessimistic at some parts of the fitted curve. Hence, if one intends to use the fitted model for predictive purposes, one may also want to model the spread of the results so that it reflects the available data more closely. Such a modeling depends very much on the particular application. In the present example, using a spread model that is of second degree in $Q$, and symmetric about the fitted line one obtains the result shown in Figure 10. It is probably more reasonable for predictive purposes than the result shown in Figure 7.

6. SUMMARY AND CONCLUSIONS

This article exposes several possible fuzzifications of model fitting, and treats in detail the fitting of a crisp model to fuzzy vector data. The result is a fuzzy fitted model, whereby the fuzziness of the model depends on the fuzziness of the data.

The data type is specialized to fuzzy vectors with conical membership functions. The restriction to conical functions greatly facilitates the numerical treatment of the problem, and a simple spread propagation formula can be derived for such functions. A new concept is the discord between two fuzzy vectors. It is a dimensionless and symmetric measure of the separation of the vectors. A complementary new concept is the grade of collocation of two elements of a fuzzy vector space.

The restriction to conical membership functions permits one to use
available model fitting computer programs with little changes. The quality of the fit is characterized by a discord between data and fitted model and a grade of compatibility between data and model. Both concepts naturally arise from the problem formulation. If the grade of compatibility is not as high as desired, then one can either try a different model, or increase the fuzziness of the data and/or of the fitted model, such that it becomes compatible with the data. The factors which achieve this are defined as data and model spread dilators, respectively, and explicit approximate formulas are derived for their calculation. The values of the dilators depend on the desired grade of compatibility, as well as on the data and their membership functions.

The application of model fitting to fuzzy data is likely to be in problems with scarce data and little information about data distribution. The description of the observed event by a fuzzy function, as derived in this paper, explicitly exposes the lack of exact information. A proper quantitation of this deficiency is achieved by the use of model dilators. The restriction of the algorithms to conical membership functions is likely not a serious impediment: because of the simplicity of the algorithms one easily can carry out the model fitting with different estimates of data spreads and, comparing the results, determine the significance of such estimates.

In summary, the described model fitting provides realistic representation of events about which only fuzzy information is available.

The dilators $\phi$ are not included in the quoted values of the spreads $s_a$ and $s_b$. The $c_{ab}$ are the concordances between the components $a$ and $b$ of the parameter vectors. The units of $a$, $s_a$, $b$ and $s_b$ are m/s.
### Table III. Model Fitting Results for Normal Impact Data Constant Model

| Projectile   | $|c'|_x$ | $|c'|_F$ | Discord grade | Data Dilator | Model Dilators |
|--------------|-------|-------|--------------|--------------|----------------|
| Flat         | 0.436 | 0.891 | 0.293        | 0.707        | 0.418          |
| Hemispherical| 0.536 | 1.095 | 0.360        | 0.640        | 0.514          |
| Short Cone   | 0.324 | 0.662 | 0.218        | 0.789        | 0.311          |
| Long Cone    | 0.484 | 0.989 | 0.325        | 0.675        | 0.464          |
| Full Cone    | 0.393 | 1.928 | 0.327        | 0.673        | 0.467          |

| Projectile   | $|c'|_x$ | $|c'|_F$ | Discord grade | Data Dilator | Model Dilators |
|--------------|-------|-------|--------------|--------------|----------------|
| Flat         | 0.084 | 0.114 | 0.048        | 0.952        | 0.069          |
| Hemispherical| 0.225 | 0.378 | 0.141        | 0.859        | 0.202          |
| Short Cone   | 0.157 | 0.302 | 0.103        | 0.897        | 0.143          |
| Long Cone    | 0.041 | 0.061 | 0.025        | 0.975        | 0.035          |
| Full Cone    | 0.135 | 0.222 | 0.084        | 0.916        | 0.120          |

The dilators are calculated for a desired compatibility grade of 0.3.

This Laboratory undertakes a continuing effort to improve the quality of the reports it publishes. Your comments/answers to the items/questions below will aid us in our efforts.

1. BRL Report Number______________________________ Date of Report______________________________

2. Date Report Received______________________________

3. Does this report satisfy a need? (Comment on purpose, related project, or other area of interest for which the report will be used.)

4. How specifically, is the report being used? (Information source, design data, procedure, source of ideas, etc.)

5. Has the information in this report led to any quantitative savings as far as man-hours or dollars saved, operating costs avoided or efficiencies achieved, etc? If so, please elaborate.

6. General Comments. What do you think should be changed to improve future reports? (Indicate changes to organization, technical content, format, etc.)
