Robustifying the Kalman Filter

Gaver, D. P. and Jacobs, P. A.

Kalman filters are tracking and prediction algorithms based on Gaussian measurement errors and structural models. The Kalman filter performance may degrade if the measurement errors come from a thicker-tailed than Gaussian distribution. In this report non-linear procedures are described which are based on Kalman-type models, but work with student-t measurement errors. This is an initial paper intended to report an approach; extensions are under development. Comments are welcome.

Note: Since this report was finished comments were received by Mike West that clarify and should improve upon his approximation of our Section 3, and upon ours as well. More work is in progress.
ROBUSTIFYING THE KALMAN FILTER;
Protection Against Symmetrically Straggling Measurement Errors

D. P. Gaver
P. A. Jacobs

1. INTRODUCTION.

Tracking and prediction algorithms based on simple Gaussian (normal distribution) measurement errors and structural models are commonly used in practice under the name of KALMAN Filters. If (a) measurement errors are not suitably Gaussian, e.g., if occasional outliers occur or (b) true structural behavior is not simple, perhaps displaying apparently discontinuous behavior caused by unfavorable sensor-target orientation, then traditional filter performance may dramatically degrade. In this paper, we will propose and study procedures based on an elaborated model of the KALMAN-type but with the measurement errors coming from a family of possibly suitable non-Gaussian distributions (e.g., Student-t) to represent, and suitably compensate for more-thick-tailed-than-Gaussian measurement error, i.e., distributions with long straggling tails having the tendency to produce symmetric outliers.

In particular the basic stochastic model considered here is

\[ \theta_n = \theta_{n-1} + \omega_n \]  
\[ Y_n = \theta_n + \epsilon_n \]  

where \( \{ \omega_n \} \) are independent normal/Gaussian random variables with mean 0 and variances \( \{ \tau_n \} \) and \( \{ \epsilon_n \} \) are independent random variables having mean 0.

The random variable \( \theta_n \) is unobservable. The random variable \( Y_n \) is interpreted as the observation of \( \theta_n \) made with measurement error \( \epsilon_n \); \( \epsilon_n \) is not Gaussian, but controllably long-tailed. The problem is to estimate \( \theta_n \) from \( Y_1, \ldots, Y_n \) in the simple recursive fashion that characterizes the classical KALMAN filter. Expression (1.1) is a simple random walk and does not represent very interesting dynamics, but does provide suggestive illustrations.

In the next, or second, section, we will describe a procedure, the ALMA (standing for KALMAN with outliers suppressed), which is based on a model in which the components of the error sequence \( \{ \epsilon_n \} \) have a Student-t distribution.
In the third section, the traditional KALMAN procedure will be described. It is based on the assumption that components of \( \{e_n\} \) have iid normal distributions. Finally, a robust procedure due to West [1981] will be described.

In section 4 results of an extensive simulation experiment will be presented and discussed. The simulation experiment compares the various procedures. The results indicate that the ALMA procedure is significantly better than the KALMAN when the true measurement error distribution is Student-t. Further, there is not much lost in using the ALMA procedure instead of the KALMAN when the true measurement error distribution is normal.

2. THE ALMA FILTER AND RELATED PROCEDURES.

While many measurement errors of physical quantities are approximately normal, especially "in the middle" of their distribution, there can well be thicker-than-normal/Gauss tails and also occasional extreme outliers; that these can have seriously degrading effects in regression-like problems has been the subject of considerable research; we cite books by Mosteller and Tukey (1977), Huber (1981), Hampel (1986); in the time-series context the article by Martin and Yohai (1986), which contains many references; also lately the articles by West and his associates (1981,1985); it is to West's approach that our methodology should best be compared.

One way to model these features is to extend the tails of the normal by continuous scale mixing. Such an approach can lead to the Student-t form, and to many other useful forms as well. We will assume here that \( \{e_n\} \) are independent random variables, now having in the Student-t distribution with mean 0, scale \( \sigma_n \) (not the standard deviation) and \( d \) degrees of freedom; that is,

\[
p_{e_n}(u) = c(d) \frac{1}{\sigma_n} \left[ 1 + \left( \frac{u}{\sigma_n} \right)^2 \right]^{-\frac{d+1}{2}}. \tag{2.1}
\]

Let \( y_i \) denote the \( i \)th measurement and \( y^n = (y_1, \ldots, y_n) \). Assume that \( \theta_n \mid y^{n-1} \) has a normal distribution with mean \( m_{n-1} \) and variance \( \Sigma_{n-1} \). Since \( \omega_n \) is assumed to have a normal distribution with variance \( \tau_n \), \( \theta_n \mid y^{n-1} \) has a normal
distribution with mean $m_{n-1}$ and variance $C_n = C_{n-1} + \tau_n$. Thus, from (1.1), (1.2), and (2.1)

$$
P\{\theta_n \in d\theta, Y_n \in dy \mid Y_1 = y_1, ..., Y_{n-1} = y_{n-1}\}
$$

$$
= \int \exp \left\{ \frac{1}{2} \frac{(\theta - m_{n-1})^2}{C_n} - \frac{1}{2} \frac{1}{(d+1)} \ln \left[ 1 + \left( \frac{\theta - y}{\sigma_n} \right)^2 \frac{1}{d} \right] \right\} d\theta dy
\tag{2.2}
$$

$$
= K \exp \left[ \frac{1}{2} \frac{(\theta - \mu(y))^2}{C(y)} + \frac{1}{2} Q(y) \right] d\theta dy
$$

where the approximation replaces the expression in the exponent by an approximating quadratic in $\theta$.

2.1 The ALMA Procedure.

The ALMA procedure provides a Gaussian approximation to the distribution of $\theta_n \mid y^n$, but one that emphatically differs from the classical linear-in-observations form. Following an argument in Gaver et al. [1986], differentiate both sides of (2.2) with respect to $\theta$ to obtain

$$
\frac{\theta - \mu(y)}{C(y)} = \frac{\theta - m_{n-1}}{C_n^\#} + \frac{d+1}{d} \frac{\theta - y}{\sigma_n^2} \frac{1}{1 + \left( \frac{\theta - y}{\sigma_n} \right)^2 \frac{1}{d}}. \tag{2.3}
$$

Equating the terms involving $\theta$ results in the following equation:

$$
\theta: \frac{1}{C(y)} = \frac{1}{C_n^\#} + w(y) \frac{1}{\sigma_n^2} \tag{2.4}
$$
where the weight
\[ w(y) = \frac{d+1}{d} \frac{1}{1 + \left( \frac{\theta - y}{\sigma_n} \right)^2} \cdot \quad (2.5) \]

Furthermore, equating the constant terms results in
\[ \frac{\mu(y)}{C(y)} = \frac{m_{n-1}}{C_n} + w(y) \frac{y}{\sigma_n^2} \cdot \quad (2.6) \]

The ALMA procedure approximates \( \theta_n | y^n \) by the normal distribution having mean
\[ m_n = C_n \left[ \frac{m_{n-1}}{C_n} + w(y_n) \frac{y_n}{\sigma_n^2} \right] \quad (2.7) \]
and variance
\[ C_n = \left[ \frac{1}{C_n} + w(y_n) \frac{1}{\sigma_n^2} \right]^{-1} \quad (2.8) \]
where
\[ w(y_n) = \frac{d+1}{d} \frac{1}{1 + \left( \frac{\theta - y_n}{\sigma_n} \right)^2} \cdot \quad (2.9) \]

Note that the weight \( w(y_n) \) involves the unknown \( \theta \). One implementation uses approximate weights of the form
\[ w_k(y_n) = \frac{d+1}{d} \frac{1}{1 + \left( \frac{y_n - m_{n-1}}{\sigma_n} \right)^2} \cdot \quad (2.10) \]

When \( k=1 \), \( m_{n-1} \) is used in place of \( \theta \) in (2.9).
When \( k=\frac{1}{2} \), \( 0.5(m_{n-1} + y_n) \) is used in place of \( \theta \).
The basic ALMA procedure is to evaluate \( w_k(y_n) \) and then use it to find

\[
C_n = \left[ \frac{1}{C_n} + \frac{w_k(y_n)}{\sigma_n^2} \right]^{-1}
\]  

(2.11)

and

\[
m_n = C_n \left( \frac{m_{n-1}}{C_n} + \frac{w_k(y_n)Y_n}{\sigma_n^2} \right).
\]  

(2.12)

The point estimate of \( \theta_n \) given \( y^n \) is \( \hat{\theta}_n = m_n \) and an estimate of the variance of \( \theta_n \) is \( C_n \). Thus the procedure provides a particular Gaussian posterior approximation. In other similar contexts, non-linear filters for example, it has been suggested that the procedure (2.10) - (2.12) be iterated with the newly-computed \( m_n \), replacing \( m_{n-1} \) in (2.10) - (2.12) in each iteration. In the simulations 0, 1 and 2 iterations were implemented, and the results compared.

2.2 The Biweight.

The ALMA procedure is an iterative reweighting procedure. In the ordinary regression context another weight has been suggested: the so-called (Tukey) biweight, cf. Mosteller and Tukey (1977). In our context, the biweight procedure can replace the weight \( w_k(y) \) in the ALMA procedure with the biweight

\[
w_B(y) = \begin{cases} 
1 - k \left( \frac{(y-m_{n-1})[\alpha\sigma_n\sqrt{\frac{d}{d-2}}]^{-1}}{\sigma_n} \right)^2 & \text{if } k \left( \frac{(y-m_{n-1})[\alpha\sigma_n\sqrt{\frac{d}{d-2}}]^{-1}}{\sigma_n} \right) < 1 \\
0 & \text{otherwise.}
\end{cases}
\]  

(2.13)

The variance of a Student-t distribution with \( d \) degrees of freedom and scale \( \sigma \) is \( \sigma^2 \frac{d}{d-2} \) if \( d>3 \), otherwise being infinite. Hence the (bi)weight \( w_B(y) \) uses the measurement \( y \) if \( |y| \) is within a standard deviations of \( m_{n-1} \), the estimate of \( \theta_{n-1} \). The weight is zero if the deviation is greater.

As was done in the basic ALMA procedure, 0, 1, and 2 iterations of (2.10)–(2.12) were tried, with \( w_B(y_n) \) replacing \( w_k(y_n) \), for values of \( \alpha=5, 7, 9 \) and \( k=1, 0.25 \).
2.3 Aspects of the Likelihood Procedure.

It is possible for the likelihood function (2.2) to exhibit two local \( \theta \)-maxima. In such a case, the likelihood procedure approximates the local maxima and chooses the one which globally maximizes the likelihood.

To examine the details let

\[
f(\theta) = \frac{d}{d\theta} \ln P(\theta_n \in d\theta, Y_n \in dy)
\]

\[
= \left( \frac{\theta \cdot m_{n-1}}{C_n^*} \right) + \frac{d+1}{d} \left[ 1 + \left( \frac{y - \theta}{\sigma_n} \right)^2 \right]^{-1} \frac{y - \theta}{\sigma_n^2} \right) d\theta dy.
\]

Now it is clearly possible for \( f(\theta)=0 \) to have multiple roots. To be specific, \( f(\theta)=0 \) for those \( \theta \) satisfying

\[
0 = \theta^3 + \theta^2(-2y \cdot m_{n-1}) + \theta \left[ \sigma_n^2 d + y^2 + (d+1)C_n^* + 2ym_{n-1} \right] + \left[ -m_{n-1} \sigma_n^2 d \cdot m_{n-1} y^2 (d+1) y C_n^* \right].
\]

The properties of this cubic-in-\( \theta \) equation can be deduced from classical results.
Let

\[ D = \left( \frac{\bar{y} - m_{n-1}}{\sigma_n} \right)^4 \]

\[ + \left( \frac{\bar{y} - m_{n-1}}{\sigma_n} \right)^2 \left\{ 2d^2 - 5d(d+1) \frac{C_n}{\sigma_n^2} - \frac{1}{4(d+1)} \left[ \frac{C_n}{\sigma_n^2} \right]^2 \right\} \]

\[ + \left[ d + (d+1) \frac{C_n}{\sigma_n^2} \right]^3 \]

then if

- \( D > 0 \) (2.15) has 1 real root and two conjugate imaginary roots;
- \( D = 0 \) (2.15) has 3 real roots, at least two of which are equal;
- \( D < 0 \) (2.15) possesses 3 real and unequal roots.

Note that if \( d = \infty \) so that \( \varepsilon_n \) has a normal distribution, then certainly \( D > 0 \) and (2.2) has a unique maximum. If \( d < \infty \) and \( C_n^2 \sigma_n^{-2} \) is small enough, then \( D > 0 \) and once again (2.2) will have a unique maximum. If \( d < \infty \) and \( C_n^2 \sigma_n^{-2} \) is large enough (actually, larger than \( \frac{4d}{d+1} \)), then \( D < 0 \) for an interval of values of \( (y - m_{n-1})^2 \) and (2.15) will have 3 real unequal roots; in this case (2.2) will have two local maxima.
The likelihood procedure computes $D$. If $D \geq 0$ it uses the ALMA procedure with weight
\begin{equation}
 w_k(y) = \frac{d+1}{d} \left[ 1 + \left( \frac{y-m_{n-1}}{\sigma_n} \right)^2 \right]^{-1}
\end{equation}
(2.17)
to compute $\theta_n$. If $D < 0$, then two candidate estimates $\theta_1$, and $\theta_2$ of $\theta$ are computed. Both estimates are obtained via the ALMA procedure (2.7)-(2.9). One approximates weight (2.9) by setting $\theta = m_{n-1}$ as in (2.10); think of the result as prior-dominated. The other approximates weight (2.9) by setting $\theta = y$, so that $w(y) = \frac{d+1}{d}$; the result is data-determined. The likelihood function is then evaluated at each value of $\theta$: $\theta_1$ and $\theta_2$. The quoted estimate of $\theta_n$ is set equal to the $\theta_i$ that comes closest to maximizing the global likelihood; the estimate of the variance is set equal to the corresponding $C_n$.

3. THE KALMAN AND WEST PROCEDURES.

In this subsection, the traditional KALMAN procedure will be described for the model (1.1)-(1.2). A procedure proposed by West (1981) will also be discussed.

3.1 The KALMAN Procedure.

The KALMAN filter finds the estimate $\hat{\theta}_n$ of $\theta_n$ which minimizes the conditional mean square error of $(\hat{\theta}_n - \theta_n)$ given $y^n$. If $\{\varepsilon_n\}$ are independently normally distributed with mean 0 and variances $\{\gamma_n\}$, then the KALMAN filter can be viewed as a Bayesian updating procedure; see Meinhold and Singpurwalla (1983).

The Bayesian KALMAN procedure assumes $\theta_{n-1 | y^{n-1}}$ is normal with mean $m_{n-1}$ and variance $C_{n-1}$. Thus, from (1.1) $\theta_n | y^{n-1}$ is normal with mean $m_{n-1}$ and variance $C_n = C_{n-1} + \tau_n$. From (1.2)

\begin{equation}
P(\theta_n \in d\theta, Y_n \in dy \mid y^{n-1}) = K \exp \left[ -\frac{1}{2} \frac{(\theta_n - m_{n-1})^2}{C_n} - \frac{1}{2} \frac{(y-n)^2}{\gamma_n} \right] d\theta dy
\end{equation}
(3.1)
Thus \( \theta_n|y^n \) has a normal distribution with mean

\[
m_n = C_n \left[ \frac{m_{n-1}}{C_n} + \frac{y_n}{\gamma_n} \right] \tag{3.3}
\]

and variance

\[
C_n = \left[ \frac{1}{C_n} + \frac{1}{\gamma_n} \right]^{-1}. \tag{3.4}
\]

The estimate of \( \theta_n \) given \( y^n \) is then

\[
\hat{\theta}_n = m_n \tag{3.5}
\]

and an estimate of the variance of \( \theta_n \) is \( C_n \).

Comparing (3.3)-(3.4) with (2.10)-(2.12) indicates that, if \( y_n \) is close to \( m_{n-1} \), then the ALMA procedure will closely resemble the KALMAN. In particular, if \( \gamma_n = \sigma_n^2 \) and \( d \to \infty \), the 2 estimators are identical. However, if \( y_n \) is far from \( m_{n-1} \), then the ALMA procedure will tend to discount that observation, relying on its estimate of \( \theta_{n-1} \) to strongly influence its estimate of \( \theta_n \). This behavior implies that the ALMA procedure will be less quickly responsive to changes in the values of \( \theta_n \) than will be the KALMAN. This is the price paid for robustness to outlying measurement errors: KALMAN treats all changes in observations as representative of structural (\( \theta_n \)) changes; ALMA is more tentative. Of course ALMA may be tuned towards KALMAN by increasing the \( d \)-value.

3.2 The West Procedure.
West proposes an estimation procedure for $\theta_n$ given $y^n$ in the case in which the density $p_{\theta_n}$ is symmetric about 0. In the special case in which $p_{\theta_n}$ is normal, West's procedure reduces to the Kalman filter.

Once again, assume $\theta_{n-1} \mid y^{n-1}$ is normal with mean $m_{n-1}$ and variance $C_{n-1}$ so that $\theta_n \mid y^{n-1}$ is normal with mean $m_{n-1}$ and variance $C_n = C_{n-1} + \tau_n$.

$$
P (\theta_n \in d\theta, Y_n \in dy \mid Y_1 = y_1, ..., Y_{n-1} = y_{n-1}) = K \exp \left\{ \frac{1}{2} (\theta - m_{n-1})^2 \frac{1}{C_n^{#}} + \ln p_{\theta_n} (y - \theta) \right\} dy
$$

(3.6)

$$
P (\theta_n \in d\theta, Y_n \in dy \mid Y_1 = y_1, ..., Y_{n-1} = y_{n-1}) \approx K \exp \left\{ \frac{1}{2} (\theta - m_{n-1})^2 \frac{1}{C_n^{#}} + \left( \ln p_{\theta_n} (y - m_{n-1}) + g(y - m_{n-1})(\theta - m_{n-1}) \cdot G(y - m_{n-1}) \frac{(\theta - m_{n-1})^2}{2} \right) \right\} dy
$$

(3.7)

where a Taylor expansion provides

$$
g(u) = \frac{-d}{du} p_{\theta_n} (u)
$$

(3.8)

$$
G(u) = \frac{-d^2}{du^2} p_{\theta_n} (u).
$$

(3.9)

Completing the square in (3.7) results in

$$
P (\theta_n \in d\theta, Y_n \in dy \mid Y_1 = y_1, ..., Y_{n-1} = y_{n-1}) \approx K \exp \left\{ -\frac{1}{2} - \frac{1}{C_n^{#}} + G(y - m_{n-1}) \left( \theta - m_{n-1} \right) \cdot g(y - m_{n-1}) \left[ \frac{1}{C_n^{#}} + G(y - m_{n-1}) \right]^{-1} \right\}.
$$

(3.10)

Hence, $P (\theta_n \in d\theta \mid Y_1 = y_1, ..., Y_n = y_n)$ is approximated by a normal distribution having mean

$$
m_n = m_{n-1} + C_n g(y_n - m_{n-1})
$$

(3.11)
and variance
\[ C_n = \left[ \frac{1}{C_n} + G(y_n-m_{n-1}) \right]^{-1}. \] (3.12)

In the special case in which \( \varepsilon_n \) has a Student-t distribution with \( d \) degrees of freedom and scale parameter \( \sigma_n \),
\[ p_{\varepsilon_n}(u) = c(d) \frac{1}{\sigma_n} \left[ 1 + \left( \frac{u}{\sigma_n} \right)^2 \right]^{-\frac{(d+1)}{2}} \] (3.13)

\[ g(u) = \frac{d+1}{d} \left[ 1 + \left( \frac{u}{\sigma_n} \right)^2 \right] \frac{u}{\sigma_n^2} \] (3.14)

and
\[ G(u) = \frac{d+1}{d} \frac{1}{\sigma^2} \left[ 1 + \left( \frac{u}{\sigma} \right)^2 \right]^{-2} \left[ 1 - \left( \frac{u}{\sigma} \right)^2 \right]. \] (3.15)

Since \( G(y_n-m_{n-1}) \) is playing the role of a variance in (3.10), but may become embarrassingly negative for large \( u \), West suggests that it be replaced by \( \max(0,G(y_n-m_{n-1})) \); this step has been taken in the simulations that illustrate the various procedures proposed here. West suggests another possibility in West et al. (1985).

4. A SIMULATION EXPERIMENT.

All simulations were carried out on an IBM 3033AP computer at the Naval Postgraduate School. Random numbers were generated using the LLRANDOMII random number package; cf. Lewis and Uribe (1981).

For each replication of the simulation the model of (1.1)-(1.2) is generated for \( n=0,1,\ldots,100 \). In the simulations reported below \( \{ \omega_n \} \) are iid normal with
mean zero and variance one. For each replication, estimates \( \hat{\theta}_n \) of \( \theta_n \) given \( y^n \) are computed using each of the procedures described above. The data collected are the estimation error \( \hat{\theta}_n - \theta_n \) for \( n=25, 50, 75, 100 \) and the estimate of variance \( C_n \), \( n=25, 50, 75, 100 \). The number of independent replications is 1000.

Tables 1 and 2 report results of the KALMAN and ALMA procedures for simulations in which \( \{e_n\} \) are iid normal with mean zero and variance one. The ALMA procedure actually uses the incorrect measurement error model that \( \{e_n\} \) are iid Student-t with \( d=3 \) degrees of freedom and variance equal to one. Results for the ALMA procedure are shown for weights as in (2.10), for \( k=1.0 \) and \( k=0.25 \). The procedure was iterated 0, 1, and 2 times.

Table 1 shows statistics of \( \hat{\theta}_n - \theta_n \) for \( n=25, 50, 75, 100 \). As anticipated, the KALMAN procedure which uses the correct (normal) model exhibits the smallest variance of \( \hat{\theta}_n - \theta_n \). The ALMA procedure with \( k=0.25 \) and 0 iterations and the ALMA procedure with \( k=1 \) and 1 iteration have the smallest variances for the ALMA procedures.

Table 2 exhibits the estimates of the variance of \( \theta_n \), namely \( C_n \), for the ALMA procedure for \( n=25, 50, 75, 100 \). The KALMAN estimate of the variance is the constant 0.618 for all of these \( n \). This constant is the limiting solution to equation (3.4) with \( \tau_n = \gamma_n=1 \); that is, with \( C = \lim_{n \to \infty} C_n \)

\[
C = \frac{1}{\frac{1}{C+1} + 1}
\]

a simple quadratic with appropriate solution

\[
C = \frac{1+\sqrt{5}}{2} = 0.618.
\]

The variance of \( \hat{\theta}_n - \theta_n \) for the KALMAN procedure in Table 1 is close to the calculated 0.618.

The mean values of \( C_n \) for the ALMA procedure with \( k=0.25 \) and 0 iterations and \( k=1 \) with 1 iteration are about half that of the corresponding variances of \( \hat{\theta}_n - \theta_n \) in Table 1.
Tables 3-4 report results for a simulation in which \( \{e_n\} \) are iid Student-t with 3 degrees of freedom and variance equal to 1. Table 3 reports statistics of the estimation error, \( \hat{\theta}_n - \theta_n \), for the KALMAN, ALMA, Biweight, Likelihood, and West procedures. As usual, the KALMAN procedure assumes \( \{e_n\} \) are iid normal with mean 0 and variance 1. The other procedures assume \( \{e_n\} \) are iid Student-t with 3 degrees of freedom and variance equal to 1. The ALMA procedure with \( k = 0.25 \) and no iterations exhibits the smallest variance of \( \hat{\theta}_n - \theta_n \). The more complicated Likelihood procedure with \( k = 0.25 \) and no iterations exhibits the next-smallest variance. The ALMA with \( k = 1 \) and 1 iteration exhibits the third smallest variance.

The Biweight procedure was implemented with the constants in the weight (2.13) \( a = 5, 7, 9 \) and \( k = 0.25 \) and 1; the procedure was iterated 0, 1, and 2 times. The results for \( a = 5 \) were much worse than those for \( a = 7 \) and 9 indicating that \( a = 5 \) is not large enough to suppress outlying values; they are not reported. Iterating the biweight procedure 1 and 2 times did not improve the results for any values of \( a \). The results of Table 7 indicate that the biweight procedure with the smallest variance uses \( k = 1.0 \) and \( a = 7 \) with no iterations.

The West procedure described in West (1981) as currently implemented does not do as well as the KALMAN. The statistics of \( C_n \) in Table 4 seem to indicate that the difficulty is with the estimate of variance, \( C_n \); the fix for negative \( G(y - m) \) makes it possible for \( C_n \) to increase by one in successive times over long periods of time.

Table 4 exhibits the statistics of \( C_n \). The KALMAN procedure, the ALMA procedure with \( k = 0.25 \) and 0 iterations, the ALMA procedure with \( k = 1 \) and 1 iteration, the Likelihood procedure with \( k = 0.25 \) and 0 iterations and the Biweight with \( k = 1 \), \( a = 7 \) all have mean \( C_n \) approximately half the variance of \( \hat{\theta}_n - \theta_n \).

5. CONCLUSIONS.

The simulation results to date indicate that a satisfactory robust KALMAN=ALMA procedure utilizes the \( k = 0.25 \) weight-starting option and requires no iteration. While the above filter is about 7% less efficient than the KALMAN when measurement errors are ideally Gaussian, it is about 6% more efficient when errors are long-tailed non-Gaussian; efficiency is in terms of ratios of estimated variances and is not the only meaningful criterion.
Examination of Table 3 reveals through values of skewness, and kurtosis, that as anticipated, the robust ALMA estimation errors are substantially more closely Gaussian than are the corresponding KALMAN products when measurement errors are Student-t.
