PREDICTING TRANSFORMS OF STABLE NOISE
AND
OTHER GAUSSIAN MIXTURES

by
Raoul LePage

Technical Report No. 193
July 1987
Stationary stable processes that are Fourier transforms of symmetric stable independent increments processes are shown to have a.s. finite conditional expectation of $X_t$ given $X_s$ and conditional variance of $X_t$ given $X_{t-\delta}, X_{t-2\delta}$. The associated conditional expectation predictors are nonlinear in $\{X_s, s(t)\}$ but are mixtures of predictors of the usual type based on the Gaussian model.

Stationary stable processes that are Fourier transforms of symmetric stable independent increments processes are shown to have a.s. finite conditional expectation of $X_t$ given $X_s$ and conditional variance of $X_t$ given $X_{t-\delta}, X_{t-2\delta}$. The associated conditional expectation predictors are nonlinear in $\{X_s, s<t\}$ but are mixtures of predictors of the usual type based on the Gaussian model.
INTRODUCTION

The work presented here is part of a program extending the classical theories of prediction, detection, and smoothing of signals to encompass models in which Gaussian noise is replaced by symmetric $\alpha$-stable (SaS) noise, where $0 < \alpha \leq 2$ is the index of stability. This is consistent with the full implications of the theory of errors (Levy, 1925) and includes Gaussian noise as the case $\alpha = 2$.

It is important to realise that Gaussian noise ($\alpha = 2$) results in the frequency domain models being identical with the time domain models, by Bochner's Theorem (Doob, 1953). But the same is not true for $\alpha < 2$. That is, with the notable exception of $\alpha = 2$, the class FT-SaS of processes which are Fourier transforms of SaS noise (e.g. wave motions) will not be the same as the class of processes that are the outputs of linear systems, such as ARMA models, driven by SaS noise (Cline and Brockwell, 1985). (Makagon and Mandrekar, 1987).

Substantial progress has been made on the prediction problem for processes of the FT-SaS type, i.e. stationary processes $X_t = \int e^{1t\lambda} Z(d\lambda)$ where $Z$ is an independent increments SaS process. In the course of this work a number of basic methods have been
developed which also have application to processes of the latter type, including ARMA models.

To understand the basic approach of this paper it is important to know that $2n$ i.i.d. Saa random vectors tend to separate out like $j^{-1/\alpha}$, $1 \leq j \leq n$ (LePage, Woodrofe, and Zinn, 1981), and are in general representable as mixtures of Gaussian distributions with differing covariances (LePage, 1980, appended to this report). This allows us to think of i.i.d. stable noise as inhomogenous Gaussian noise with random $\alpha/2$ stable covariances. As might be inferred from remarks made above, the consequences of this inhomogeneity when noise is in the form of wave amplitudes differ greatly from the effects of noise entering in the form of terms driving difference equations.

In recent work (Makagon and Mandrekar, 1987) there is defined the concept of a generalized spectrum for any strictly stationary stable process. In case the spectrum is given by independently scattered measure, as above, they have shown that one can obtain the linear analysis of such signals by methods analagous to those used for Gaussian processes. This extends (Cambanis and Soltani, 1982) to the case $\alpha \leq 1$ by a more general method.

However, linear prediction is not in general as good as conditional expectation prediction. The latter has not been much
studied for stable processes because of the fact that $E |X_t|$ is infinite for $\alpha \leq 1$. Surprisingly, by exploiting (LePage, 1980) we will prove for FT-SaS processes \{X_t\} that for every $\alpha$ the conditional expectations $E(|X_t| | X_s)$ and $E(X_t^2 | X_{t-\delta}, X_{t-2\delta})$ are almost surely finite. This is surprising in view of the fact that for $\alpha \leq 1$ the expectations $E |X_t|$ are infinite, and for all $\alpha < 2$ the expectations $E X_t^2$ are infinite.

As a consequence of these conditional moments existing, the conditional expectation predictor of $X_t$, regardless of the number of predicting variables, is well-defined and optimal for conditional mean squared error, provided the predicting variables include two time points of the form $t-\delta$, $t-2\delta$ for some $\delta \neq 0$. By combining these results with (Cambanis and LePage 1987) it can be shown that for $\alpha < 2$ the conditional expectation predictor $E(X_t | X_{t-\delta}, \delta \leq \delta \leq L)$ is asymptotically consistent for $X_t$ as $\delta \to 0$ (excluding 0 in the discrete case) and $L \to \infty$, whereas the linear predictor is not.

Since the above conditional expectations turn out to be a-posteriori averages of Gaussian conditional expectations computed for various covariances, these non-linear conditional expectation predictors are a smoothing of Hilbert space methods and are in fact Bayesian predictors for a naturally occurring a-priori distribution intrinsic to FT-SaS processes.
The new methods generally allow us to compute quantities previously thought to be undefined because stable r.v. lack certain moments. For example, the identity $E(X_t \mid X_s) = X_s E \cos(A(t-s))$, where $A$ is a random sample from the normalized spectral distribution function was known for $1 < \alpha \leq 2$ (Kanter and Steiger, 1974). Corollary 2.1.2 below proves this result for $0 < \alpha \leq 2$ by a totally new direct calculation which does not require existence of the unconditional expectation and bypasses differentiation of the characteristic function altogether. Certain other conditional and unconditional integrals can be directly calculated by the same method, including the integer moments of the characteristic function of the processes conditioned on the invariant sigma algebra (Cambanis and LePage, 1987).

As mentioned previously, this work is based on a representation of FT-SoS processes as mixtures of stationary Gaussian processes (with randomly chosen covariance function $\Theta$) due to (LePage, 1980). The new observation, specialized to the case $\mathcal{F} = \sigma\{X_{-1}, X_0\}$ and $X = X_1$, is that the conditional density of $(X_1, X_0)$, given the sigma field generated by the covariance function $\Theta$, cancels terms in the conditional expected squared error of prediction. This forces convergence of the conditional expectation $E^\mathcal{F}(X - E^\mathcal{F}X)^2$. Such integrals, including $E^\mathcal{F}X$, are computed as mixtures, on $\Theta$, of
\(\theta\)-specific Gaussian integrals. The indicated predictors are thus conditional mixtures of \(\theta\)-specific Gaussian linear predictors.

**STABLE PROCESSES**

The log characteristic function of any stationary Gaussian random functions having a continuous covariance takes the form

\[
\log \mathbb{E} \exp i \sum_{k=1}^{n} r_k X_{t_k} = -\left(\sigma^2/2\right) \mathbb{E} \left| \sum_{k=1}^{n} r_k \exp i t_k A_1 \right|^2.
\]

(1.1)

where \(\sigma^2 > 0\) and \(A_1\) is a random variable whose probability distribution function is the normalized spectral distribution function. Stable analogues of these laws may be obtained by replacing the exponent 2 in (1.1) by a number \(\alpha\) in the range \(0 < \alpha < 2\).

In (LePage, 1980) it was proved that the resulting characteristic functions are precisely those of the class of FT-SaS processes. The following construction for such processes was given. For each \(0 < \alpha < 2\) define r.v. \(X(t), t \in \mathbb{R}\) by

\[
X_t = \sum_{j=1}^{\alpha} \cos(A_j t + \Theta_j) Y_j^{-1/\alpha}.
\]

(1.2)

In (1.2), which converges a.s. for each \(t\), the sequence of r.v. \(\{A_j\}\) (which we denote by \(A\) for brevity) are i.i.d. from any distribution on \(\mathbb{R}\); \(\Theta\) are i.i.d. uniformly distributed on the interval \([-\pi, \pi]\); \(Y\) are i.i.d. with \(\mathbb{E} |Y_1|^{2\alpha}\) finite; \(\Gamma\) are the consecutive arrival times of a homogeneous Poisson process with unit intensity function on the time domain \(\mathbb{R}^+\); and the sequences of r.v. \(A, \Theta, Y, \Gamma\) are mutually independent.
From (LePage, 1980, Theorem 7.4) the series (1.2) converges almost surely for each $t \in \mathbb{R}$ and $0 < \alpha < 2$, and the r.v. defined by the left side of (1.2) have log characteristic function

$$2^{-\alpha} B(\alpha) C(\alpha) E|Y_1|^\alpha E|\sum_{k=1}^n r_k \exp it_\lambda A_k|^\alpha,$$

where $B(\alpha) = \alpha \int_0^\infty (\cos(r)-1) \frac{dr}{r^{1+\alpha}}$, and $C(\alpha) = \int_{-\pi}^{+\pi} |1+e^{i\eta}|^{\alpha} d\eta$.

From (1.3) it may be seen that the law of $X$ depends on the law of $Y_1$ only through the $\alpha$-th absolute moment. Taking $\{Y_j\}$ to be Rayleigh distributed, equivalent to letting $\{Y_j\}$ be complex Gaussian and taking the real part of $\{X(t), t \in \mathbb{R}\}$, yields a process $X$ which is conditionally Gaussian and stationary given the sequences $\Lambda, \Gamma$. The process given by the infinite series (1.1) may be written

$$X_t = \int_{\mathbb{R}} e^{i\lambda t} Z(d\lambda).$$

where $Z$ is, conditionally on $\Lambda, \Gamma$, a Gaussian orthogonal random set function supported on the sequence of frequencies $\Lambda$ and $-\Lambda$, with

$$Z((-\Lambda_k)) = \overline{Z((\Lambda_k))} \text{ and } Z((\Lambda_k)) \text{ given by }$$

$$= \left(\frac{1}{2}\right) \sum_{j=1}^\infty |\gamma_j|^{-1/\alpha} [I(A_j = \Lambda_k) e^{i\theta_j} + I(-A_j = \Lambda_k) e^{-i\theta_j}]. \text{ } k \geq 1. \quad (1.5)$$

From (1.2) or (1.5) it is seen that the conditional covariance function of $X$ given $\Lambda, \Gamma$, is given by

$$\theta(t) = \sum_{j=1}^{\infty} r_j^{-2/\alpha} \cos(A_j t)/2, \quad t \in \mathbb{R}. \quad (1.6)$$

That is, $\{X(t), t \in \mathbb{R}\}$ is conditionally Gaussian and stationary with covariance (1.6) given $\Lambda, \Gamma$. 

2. EXISTENCE OF CONDITIONAL MOMENTS

We require the formula $E^\mathcal{F} \eta = \int_{\mathbb{D}} (d\theta|\mathcal{F}) E^\mathcal{F} \eta$, where $\eta$ is a non-negative polynomial in the coordinate r.v. of the random function $X$, $\mathcal{F}$ is the $\sigma$-field generated by a finite number of the coordinate r.v., $E^\mathcal{F} \eta$ is the $E^\mathcal{F}$-conditional expectation given $\mathcal{F}$, and $\pi(d\theta|\mathcal{F})$ is the regular conditional probability distribution of the finite number of coordinate values of $\theta$ which appear in $E^\mathcal{F} \eta$. A proof may be given by martingale methods from the corresponding result for the discrete case which is $P(A|D) = \Sigma^P_0 P(\theta|D)|P(D) = \Sigma^P_0 P(\theta|D) P_\theta(A|D)$.

**Theorem 2.1.** Let $X$ be a random function which is a mixture of zero-mean Gaussian stationary processes. For real numbers $s,t$ the conditional expectation $E^\mathcal{F} |X_t|$ is almost surely finite, where $\mathcal{F}$ is a $\sigma$-algebra with respect to which $X$ is measurable.

**Proof.** It is enough to prove that $E^\mathcal{F} |X_0|$ is finite a.s. If $\theta(0) = 0$, then $X_0 = X_1 = 0$ almost surely. For each fixed $\theta$ with $\theta(0) > 0$, the conditional distribution of $X_1$ given $X_0$ is normal with mean $\mu(\theta,0,1) = E^\mathcal{F}_\theta X_1 = (\theta(1)/\theta(0))X_0$, and variance $\sigma^2(\theta,0,1) = \theta(0)(1-(\theta(1)/\theta(0))^2)$. Then,

$$E^\mathcal{F} |X(t)| = \int_{\{\theta(0) > 0\}} E^\mathcal{F}_\theta |X_1| \pi(d\theta|X_0) \leq \int_{\{\theta(0) > 0\}} (|\mu(\theta,0,1)| + \sigma(\theta,0,1)) \pi(d\theta|X_0).$$

(2.2)
Since \(|\theta(1)| \leq |\theta(0)|\) a.s., the \(\mu\)-term of (2.2) is a.s. finitely integrable. Now use
\[\pi(d\theta|X_0) = \pi(d\theta)\pi(X_0|\theta)\pi(X_0),\]
where \(\pi(r|\theta) = (2\pi)^{-1/2} \theta^{-1/2} \exp(-r^2/2\theta(0))\), from which it is seen that the
\(\sigma\)-term of (2.2) is also a.s. finitely integrable. \(\square\)

Corollary 2.1.1. If \(\mathcal{F}\) is a sigma algebra generated by a subset of
the random variables \(\{X(t), t \in \mathbb{R}\}\), then
\[\mathbb{E}^\mathcal{F} X_1 = \int \pi(d\theta|\mathcal{F}) \mathbb{E}_\theta^\mathcal{F} X_1,\]
which is a mixture of the \(\theta\)-specific Gaussian best linear predictors of \(X_1\) based on \(\mathcal{F}\). In particular,
\[\mathbb{E}^\mathcal{F} X_1 = \mathbb{E}(\theta(1)/\theta(0)|X_0) X_0 = (\mathcal{F}(\theta(0) > 0) \pi(d\theta|X_0)(\theta(1)/\theta(0))) X_0.\]

Corollary 2.1.2. (Cambanis-LePage). For a process of the form (1.2) with
\(0 < \alpha \leq 2\), \(E(\theta(1)/\theta(0)|X_0) = E(\cos(\Lambda_1)).\)

Proof. The case \(\alpha = 2\) is obvious. For \(\alpha < 2\), from (1.2) and (1.6)
\[X_0 = \sum_{j=1}^{\infty} \cos(\theta_j) \Gamma_j^{-1/2}\]
\[\theta(1)/\theta(0) = \sum_{j=1}^{\infty} \Gamma_j^{-2/\alpha} \cos(\Lambda_j)/\sum_{j=1}^{\infty} \Gamma_j^{-2/\alpha}.\]

Since \(\Lambda, \theta, \Gamma\) are independent and \(X_0\) is measurable \(\sigma(\theta, \Gamma)\),
\[E^\mathcal{O} (\theta(1)/\theta(0)) = E^\mathcal{O} E(\theta(1)/\theta(0)|\theta, \Gamma)\]
\[= \sum_{j=1}^{\infty} \Gamma_j^{-2/\alpha} E(\cos(\Lambda_j)/\sum_{j=1}^{\infty} \Gamma_j^{-2/\alpha}\]
\[= E(\cos(\Lambda_1)).\]

Since no special role is played by times zero and one, the formula
\[E[\theta(t)/\theta(0)|X(s)] = E(\cos(\Lambda_1(t-s))\]
follows at once. This result extends (Kanter and Steiger, 1974) to the case \(\alpha \leq 1\).
Proposition 1. There exist FT-SaS processes for which the conditional mean squared error $E_{X_0} \left( X_1 - E_{X_0} X_1 \right)^2$ is infinite.

**Proof.** Let $H(X_0) = \int (\theta(1)/\theta(0)) \pi(d\theta|X_0)$. That is, $E_{X_0} X_1 = H(X_0) X_0$. Then

$$E_{X_0} \left( X_1 - E_{X_0} X_1 \right)^2 = \int (\theta(0)>0) \theta(0) \left( 1 - \left( \theta(1)/\theta(0) \right)^2 \right) \pi(d\theta|X_0)$$

$$+ \int (\theta(0)>0) X_0^2 \left( H(X_0) - \left( \theta(1)/\theta(0) \right) \right)^2 \pi(d\theta|X_0). \quad (2.3)$$

The second term on the right of (2.3) is integrable. The first term on the right may be handled using

$$\pi(d\theta|X_0) = \pi(X_0|\theta) \pi(d\theta)/\pi(X_0)$$

$$= (2\pi\theta(0))^{-1/2} e^{-X_0^2/2\theta(0)} \pi(d\theta)/\pi(X_0). \quad (2.4)$$

From (1.6) it is seen that $\theta(0)$ possesses a stable distribution of index $\alpha/2$ under $\pi(d\theta)$. Taking $\Lambda_1$ with support in the two point set $\{-\pi/2, \pi/2\}$ ensures $\theta(1)=0$ a.s., in which case the integrand of (2.3) is, by (2.4), asymptotically of order $r^{-(\alpha+1)/2}$ at infinity. This fails to be integrable if $\alpha \leq 1$. \(\Box\)

On the other hand, the conditional expected squared error of prediction given $\mathcal{F} = \sigma(X_{-1}, X_0)$ is a.s. finite.

Theorem 2.2. Let $X$ be a random function of the form (1.2). For real numbers $r,s,t$ with $|r-s|=|t-s|$ the conditional expectation

$$E_{\mathcal{F}} \left( X_t - E_{\mathcal{F}} X_t \right)^2$$

is almost surely finite if $\mathcal{F}$ is a $\sigma$-algebra with respect to which $X_r$ and $X_s$ are measurable.
Proof. Replace $\pi(d\theta|X_0)$ by $\pi(d\theta|X_{-1},X_0) = \pi(d\theta|x)$ in (2.3), and denote by $\rho$ the correlation $\rho = \theta(1)/\theta(0)$. Then,

$$\pi(d\theta|x) \leq (\pi(d\theta)/\pi(X_{-1},X_0))(2\pi)^{-1}\theta^{-1}(0)(1-\rho^2)^{-1}.$$  

(2.5)

From theorem 2.1,

$$E^xX^2(1) = \int \pi(d\theta|x) \ E^xX^2(1) = \int \pi(d\theta|x) \ [E^x\theta(X_1-\theta X_0)^2 + (E^x\theta X_1)^2]$$  

(2.6)

The first term in the brackets of (2.6) is less than or equal to $\theta(0) (1-\rho^2)$, and is therefore $\pi(d\theta)$-integrable when multiplied by the Jacobian from (2.5). The second term in the brackets of (2.6) may, on $\rho^2 \neq 1$ be written

$$[\rho X_0 + \frac{\theta(2) - \rho \theta(1)}{\theta(0) (1-\rho^2)} (X_{-1} - \rho X_0)]^2.$$  

(2.7)

The first component in (2.7) is $\rho X_0$ whose square is integrable by $\pi((d\theta|x))$. It is therefore enough to bound

$$D(\theta) = \left\{ \frac{\theta(2) - \rho \theta(1)}{\theta(0) (1-\rho^2)} \right\}$$  

(2.8)

Let $|| \ | |$ denote $L_2$ norm with respect to the zero-mean stationary Gaussian process with covariance function $\theta$. Then

$$\theta(0) = (||X_1||^2 + ||\rho X_0||^2 + ||D(\theta) (X_{-1} - \rho X_0)||^2$$

$$= \rho^2 \theta(0) + D^2(\theta) \theta(0) (1-\rho^2).$$

Therefore $D^2(\theta) \leq 1$ on $\rho^2 \neq 1$. But on $\rho^2=1$ (2.7) is replaced by $X_0$.

Thus (2.5) is a.s. finite. Note that the Cauchy-Schwartz bound on (2.8) is inadequate. Q.E.D.

3. FUTURE DIRECTIONS
The ergodic properties of \( \{X_t\} \) are now completely understood.

In (Cambanis and LePage, 1987), subject to mild conditions on the spectral distribution, a complete characterization of the invariant sigma field of the process \( \{X_t\} \) is obtained in terms of amplitude and frequency variables measurable with respect to the remote past. The non-ergodic component is identified with i.i.d. uniformly distributed phase variables.

Using the above results, it follows that under rather weak conditions the predictors \( \mathbb{E}(X_t \mid X_{t-\delta}, \delta_0 \leq \delta \leq L) \) converge almost surely to \( X_t \) (and conditionally in mean square given the random spectral amplitudes) as \( L \to \infty, \delta_0 \to 0 \). Thus, the action of SoS noise in wave amplitudes is to make prediction ultimately more perfect than would be the case for Gaussian noise. Since by a result of (Makagon and Mandrekar, 1987) linear prediction optimized for the given FT SoS distribution is only consistent for \( X_t \) under very exceptional conditions on the spectral measure, it follows that linear prediction is inferior to conditional expectation prediction for \( \alpha < 2 \). Such results generalize easily to the multiparameter and \( \dim > 1 \) cases, and will apply to certain types of spatial processes which are Fourier transforms.

By contrast with the above, linear prediction for linear system SoS processes, such as ARMA(p,q) models driven by i.i.d. SoS random
vectors, is intrinsically interesting due to the way in which the noise enters additively. The conditional expectations \( \mathbb{E}(X_t \mid X_s, s < t) \) are a.s. infinite except in trivial cases due to \( \mathbb{E}(|\epsilon_t| \mid X_s, s < t) = \infty \), i.e. the conditional expectation of the independent error. By Theorem 2.1 it follows that such processes cannot be of the FT SøS type.

If it can be proved that \( \mathbb{E}(|\epsilon_r| \mid X_s, s < t) < \infty \) a.s. for all \( r < t \), then an obvious choice for non-linear prediction will be to predict the value zero for \( \epsilon_t \) and use the conditional expectation predictor on \( \epsilon_r, r < t \). This most promising approach is currently under study.

Abstract

Elementary series constructions, involving a Poisson process, are obtained for multidimensional stable variables and random functions. Symmetric stable laws are shown to be mixtures of Gaussian laws.

Key words and phrases. Stable, series representation, Poisson process.
1. **Introduction.**

Series decompositions, involving the arrival times of a Poisson process, have been given by Ferguson and Klass [1] for the non-Gaussian component of an arbitrary (real-valued) independent increments random function on the unit interval. LePage and Woodroofe and Zinn [4] have rediscovered a variant of this decomposition in connection with their study, via order statistics, of the limit distribution for self-normalized sums (e.g., Students' $t$), when sampling from a distribution in the domain of attraction of an arbitrary stable law of index $\alpha > 2$.

The present paper obtains a characterization of stable laws on spaces of dimension greater than one. This characterization is formally like that of Ferguson-Klass for dimension one, but with i.i.d. vector multipliers on the Poisson terms. The law of these coefficients may be chosen proportional to the Lévy measure, although this is not necessary. These results take a particularly elegant form in the case of symmetric stable laws, where a calculus is developed showing:

1. which Lévy measure associates with vector coefficients other than the aforementioned one, still what happens when independent stable laws are linearly combined as in a weighted sum, will lead to construct an appropriate multidimensional independent increments symmetric stable set.
function, and (iv) how to construct an arbitrary harmonizable stationary symmetric stable random function having multidimensional domain and/or range. Symmetric stable laws are shown to be mixtures of Gaussian laws.

Partly because of the self-contained character of Kuelbs' paper [3], in which the characterization of the log-characteristic function of a stable law is extended to real separable Hilbert space, the Hilbert space level of generality has been chosen for this paper. Later extensions of Kuelbs' result to Banach and more general spaces support a corresponding generalization of these results. In addition to Kuelbs' result we need a method employed by Ferguson and Klass to transform certain dependent series into eventually identical independent ones. We also require standard results giving conditions under which an independent series in Hilbert space converges almost surely (e.g. [2], Theorem 5.3). The rest of the paper is basically self-contained and affords a surprisingly accessible and clear view of $\alpha < 2$ stable laws, and random functions, based on elementary series constructions.

Part II of this paper will generalize these results to the infinitely divisible case.
2. Notation.

The following symbols and conventions will be in force throughout this paper.

\[(2.1)\]

\[\sim\] "is asymptotic with"

\[\Delta\] "equals by definition"

\[\overset{D}{\rightarrow}\] "has the same distribution as"

\[\Rightarrow\] "converges in distribution to"

\[\alpha\] \(0 < \alpha < 2\), an index of stability

\[\{\Gamma_j, j \geq 1\}\] arrival times of a Poisson process with unit rate

\[H\] a real separable Hilbert space

The material of the next section is drawn from \[4\].

Limit theorems are not the subject of this paper. However, we should not proceed without benefit of the following example, which exposes some connections between $\alpha < 2$ stable r.v. and the Poisson process.

Let $\{\varepsilon_j, j \geq 1\}$ be independent of the sequence $\Gamma$ and i.i.d. with $P(\varepsilon_1 = 1) = P(\varepsilon_1 = -1) = \frac{1}{2}$, and define $G(x) \triangleq x^{-\alpha}, \forall x \geq 1$.

Think of $G(x) = P(\frac{1}{2} \leq x) \forall x \geq 1$, where $X$ is a r.v. symmetrically distributed about zero. We will construct particular r.v. $X_1, \ldots, X_n$, i.i.d. as $X$, whose normalized sums converge in distribution to the symmetric stable law of index $\alpha$. To do this, use the arrival times of a Poisson process to generate uniform order statistics, apply $G^{-1}$ to these, multiply by the signs $\varepsilon_j$, and permute. As constructed, the normalized sums will actually converge almost surely to $\frac{1}{n} \sum_{j=1}^{\infty} \varepsilon_j^{-1/2}$ (see (3.1) below), a series possessing the symmetric stable law of index $\alpha$.

In fact, a direct proof of the stability of $\frac{1}{n} \sum_{j=1}^{\infty} \varepsilon_j^{-1/2}$ follows easily from the observation that the arrival times of several (say $K > 1$) independent unit rate Poisson processes (run simultaneously) constitute $K^{-1}$ times the arrival times of a unit rate Poisson process. This argument works just as well for $\varepsilon$ replaced by any vector sequence (provided the series converges) and suggests the multivariate extensions of sections 4 and 5.

For each $n > 1$ let $U_1(1) \leq U_1(2) \leq \cdots \leq U_1(n)$ denote the order statistics of i.i.d. random variables $U_1, \ldots, U_n$ which are
uniformly distributed on $[0,1]$. Then for each fixed $n > 1$, letting
\[ X_j \overset{\Delta}{=} \varepsilon_j G^{-1}(U_j), \forall j \geq 1, \]

\[ \sum_{1}^{n-1} \varepsilon_j x_j \overset{\mathbb{D}}{\rightarrow} n - \frac{1}{\alpha} \sum_{1}^{n} \varepsilon_j G^{-1}(U_{(j)}) \]

\[ = n^{-1/\alpha} \sum_{1}^{n} \varepsilon_j (j) \]

\[ = n^{-1/\alpha} \sum_{1}^{n} \varepsilon_j (\frac{T_j}{n+1})^{-1/\alpha} \]

\[ = n^{-1/\alpha} \sum_{1}^{n} \varepsilon_j (\frac{T_{n+1}}{n})^{1/\alpha} \]

\[ \overset{\text{a.s.}}{\rightarrow} 1 \] (SLLN)

\[ \sum_{1}^{\infty} \varepsilon_j \overset{\text{a.s.}}{\rightarrow} 1 \]

It is convenient to refer to $\varepsilon_j \tilde{\Gamma}_j, j \geq 1$ as the residual order statistics, keeping in mind that the ordering is on decreasing absolute values.

The same example suggests an invariance principle (proved in [4]) for self-normed sums such as $\sum_{1}^{n} X_j / \sqrt{\sum_{1}^{n} X_n^2}$ which, regardless of $\alpha$, converge in distribution to a limit law depending only on the stable attracting $X_1$. For the r.v. constructed above, $\forall n \geq 1$,

1. Use $\frac{\Gamma_j}{\tilde{\Gamma}_j}$ and $\sum_{1}^{\infty} j^{-2/\alpha} < \infty$ a.s., and apply the 3-series theorem conditional on the sequence $\Gamma$. 

5
That is, the limit law of the \( t \)-statistic\(^2\) is that of the \( t \)-statistic calculated on the residual order statistics (see also [6]).

Even the construction of stable independent-increments processes can be motivated by means of the same example. We restrict our attention to the homogeneous increments case. Let \( [T_j, j \geq 1] \overset{\mathbb{D}}{=} [U_j, j \geq 1] \), and suppose the sequences \( T, \epsilon, \Gamma \) are mutually independent. The partial sum processes \( \sum_{1}^{[nt]} X_j, \ 0 \leq t \leq 1, \forall n \geq 1 \) can be effected by independent selections of \( X_1, \ldots, X_n \) into subsets of sizes \( [nt] \) using multiplication by indicators:

\[
I_{n}^{(n)}(t) = I(T_1 \leq \frac{[nt]}{n})
\]

\[
I_{jj}^{(n)}(t) = I(T_j \leq \frac{[nt] - \frac{[nt]}{n} I_{1}^{(n)}(t)}{n+1-j}), \forall 1 \leq j \leq n.
\]

Then for each \( n \geq 1 \),

\[
(n^{-1/2} \sum_{1}^{[nt]} X_j, \mathbb{tc}[0,1]) \overset{\mathbb{D}}{=} \left\{ \sum_{1}^{n} I_{j}^{(n)}(t) \varepsilon j_{j}^{[-1/2]} \left( \frac{n+1}{n} \right)^{1/\alpha}, \mathbb{tc}[0,1] \right\}
\]

\( \varepsilon j_{j}^{[-1/2]} \left( \frac{n+1}{n} \right)^{1/\alpha}, \mathbb{tc}[0,1] \).

Details of this argument are unpublished.

\(^2\) The square of this \( t \)-statistic is simply related to the square of Students'\( -t \), and both have the same limit law.

Suppose $\{X_j, j \geq 1\}$ are i.i.d. random vectors in a real separable Hilbert space $H$ and that the sequences $X$, $\Gamma$ are independent. For each $n \geq 1$ denote by $K_n$ the number of arrival times $\Gamma$ in the interval $[0,a_n]$, $a_n = \sum_{j=1}^{n} j^{-1}$. This choice of $a_n$ is from [1]. Its advantages will be apparent in what follows.

Remark. Sums of the kind $\sum_{j=1}^{n} k_j$ are for each $n \geq 1$ defined to zero on the event $K_n = 0$. Use $(\cdot, \cdot)$, $\|\cdot\|$, to denote $H$ inner product and norm.

For each $n \geq 1$, $x \in H$, $c > 0$, (see also [1], pg. 1639),

$$\mathbb{E} e^{\sum_{j=1}^{K_n} i(x,cX_j) r^{-\alpha} j} = \mathbb{E} e^{\sum_{j=1}^{K_n} i(x,cX_j) r^{-\alpha} j}$$

(4.1) $\mathbb{E} e^{\int_{0}^{a_n} (x,X) t^{-\alpha} dt} = e^{\int_{0}^{a_n} (x,X) t^{-\alpha} dt}$

Kuelbs ([3], lemma 2.2) has proved that the log-characteristic function of a (non-Gaussian) stable probability measure on $H$ is necessarily of the following form, for a unique $\xi \in H$ and finite Borel measure $\sigma$ on $S : \xi H$ and finite $||x|| = 1$.
(4.2) \[ i(x, \theta) + \int_S \int_0^\infty (e^{i(x,s)r} - 1 - i(x,s)r) \frac{dr}{1 + r^2} \sigma(ds), \forall x \in \mathbb{H}. \]

It is convenient to refer to:

(4.3) expression (4.2) with $\theta = 0$.

Define $\delta \triangleq \sigma(S)$, $\mu \triangleq \sigma/\delta$, and

\[ \beta_n \triangleq \int_S \int_0^\infty \left( \delta^{-1/\alpha} \right) \left( -\frac{1}{\alpha} \right) \frac{dr}{1 + r^2} \sigma(ds), \forall n \geq 1. \]

Lemma 4.4 If (4.3) is the characteristic function of a stable law on $\mathbb{H}$ and if the sequence $\{X_j, j \geq 1\}$ is i.i.d. $\mu$ and independent of the sequence $\Gamma$, define

\[ x(n) \triangleq \left( \sum_{1}^{K_n} X_j^{-1/\alpha} \right)^{-1/\alpha} X_j^{-1/\alpha}, \forall n \geq 1. \]

Then $\forall x \in \mathbb{H}$, $E \exp i(x, X_n)$ converges to (4.3).

Remark. This result is not altogether satisfactory since convergence of the series $\{x(n), n \geq 1\}$ is through stochastic times $\{K_n, n \geq 1\}$, and is not yet a.s. in $\mathbb{H}$. These defects are remedied in Theorem 4.8 below.

Proof. For each $x \in \mathbb{H}$, $n \geq 1$, by (4.1),
\[ (4.5) \quad \log_e E e^{i(x,x^{(n)})} = -i(x, \beta_n) + \sum_{\alpha=1}^{\infty} \int_{\alpha^{-1/\alpha}}^{\infty} (e^{i(x,s)\tau - 1} - 1) \frac{ds}{\tau^{1+\alpha}} \]

\[ = \sum_{\alpha=1}^{\infty} \int_{\alpha^{-1/\alpha}}^{\infty} (e^{i(x,s)\tau - 1} - 1) \frac{ds}{\tau^{1+\alpha}} \sigma(ds) \]

\[ = (4.3) \quad \square \]

From ([1], lemma 2), we conclude that

\[ \left\{ \begin{array}{l}
K_{n+1} X_{j}^{1 - 1/\alpha} \\
K_{n} X_{j}^{1 - 1/\alpha}, \quad n \geq 1
\end{array} \right\} \]

are independent. Furthermore, using an argument drawn from [4], \( \forall n > 1, \)

\[ (4.6) \quad \frac{E \left\| \sum_{1}^{K} x_{j}^{1 - 1/\alpha} \right\|^2 \leq a^{-2/\alpha} \frac{E(K_{n+1} - K_{n})^2}{n} \leq \frac{2}{n(\log_e n)^{2/\alpha}} \]

which is summable in \( n. \) Therefore,

\[ \sum_{1}^{K} x_{j}^{1 - 1/\alpha} - E \sum_{1}^{K} x_{j}^{(1 - 1/\alpha) \wedge 1} \]

converges in probability in \( H. \) A short calculation gives
\[ A(n, \delta) \triangleq \mathbb{E} \alpha^{-1/\delta} \frac{1}{\alpha} r_{1}^{-1/\alpha} \mathcal{L}_{1} - \delta \int_{\alpha^{-1/\delta}}^{\infty} \frac{r}{1+r^{2}} \frac{dr}{r^{1+\alpha}} \]

Further, let

\[ \frac{3.}{\alpha^{-1/\delta} \frac{1}{\alpha} \int_{0}^{\alpha}((t^{-1/\alpha} \mathcal{L}_{1}) - \frac{t^{-1/\alpha}}{1+\alpha^{-2/\alpha} 2/\alpha t^{-2/\alpha}}) \ dt} \]

+ finite limit \( \triangleq A(\alpha, \delta) \) as \( n \to \infty \).

Therefore \( X^{(n)} \) converges in probability.

**Theorem 4.8.** If \( (4.3) \) is the log characteristic function of a stable law on \( H \), then the series

\[ \alpha^{-1/\delta} \frac{1}{\alpha} r_{1}^{-1/\alpha} \mathcal{L}_{1} \mathcal{X}_{j} - \frac{1}{\alpha} \mathcal{E}_{1} \int_{j-1}^{j} \frac{t^{-1/\alpha}}{1+\alpha^{-2/\alpha} 2/\alpha t^{-2/\alpha}} \ dt \]

converges a.s. in \( H \) to a random vector with log characteristic function \( (4.3) \).

**Remark.** Centering is not needed for the case \( \alpha < 1 \), nor is it needed for the symmetric case which will appear in [4].

**Proof.** Since \( X^{(n)} \) converges in probability and \( X^{(n)} \) is an independent series, we conclude by ([2], Theorem 5.3(6)) that \( X^{(n)} \) converges a.s. in \( H \). Recall that with probability one \( \exists \) finite \( M \) such that \( (n \geq M) \Rightarrow (\exists \) smallest \( N(n) \) with \( n = K_{N(n)} \). Then \( \forall n \geq n, \)

\[ \text{The first term equals the first term above. For the second term use } t = \alpha^{-1/\delta} r^{-\alpha} \]

10
\begin{equation}
\chi(N(n)) = a^{-1/\alpha} \int_1^{N(n)} \frac{1}{x_{1j}^{\alpha}} \left( -1/x_j^{1/2} \right) dt + (\mathbb{E}X_1) A_n(z, \zeta) + o(1).
\end{equation}

Since for \( n \geq M, \ (n = K(n) \Rightarrow (a_n^{-1} < n \leq a_n) \),

\begin{equation}
\left| \int_{r_n}^{a_n N(n)} (t^{-1/\alpha} \wedge 1) dt \right| \leq (N(n))^{-1} \Rightarrow 0.
\end{equation}

By the law of the iterated logarithm, a.s. eventually as \( n \to \infty \)

\begin{equation}
\left| \int_{r_n}^{a_n N(n)} (t^{-1/\alpha} \wedge 1) dt \right| \leq \int_{r_n}^{a_n N(n)} t^{-1/\alpha} dt \leq \int_{r_n}^{a_n N(n)} (n : r_n)^{-1/\alpha} dt \leq 2 \sqrt{n \log \log n} (n + o(n))^{-1/2} \to 0.
\end{equation}

Therefore,

\begin{equation}
\chi(N(n)) = a^{-1/\alpha} \frac{1}{x_{1j}^{\alpha}} \int_1^{N(n)} \frac{1}{x_j^{1/2}} dt - (\mathbb{E}X_1) \int_0^{a_n N(n)} (t^{-1/\alpha} \wedge 1) dt + A\left(\alpha, \zeta\right)(\mathbb{E}X_1) + o(1),
\end{equation}

which converges a.s. in \( H \) to a random vector with log characteristic function (4.3). \( \Box \)

Remark. The centerings used above also have an interpretation involving \( (\mathbb{E}X_1) E(n^{-1/\alpha} \cdot 1) \), which will not be given here.
5. **Symmetric Case, Multiple Representations.**

In this section we do not assume that \( X_1 \) is distributed according to the measure \( \mu \), or even restrict its distribution to \( S \). Suppose \( X, \varepsilon, \Gamma \) are mutually independent sequences, with \( \varepsilon, \Gamma \) as in section 3, and \( \{X_j, j \geq 1\} \) i.i.d. in \( H \) with \( E\|X_1\|^\alpha < \infty \).

**Remark.** Series of form \( \sum_{j=1}^\infty \varepsilon_j X_j^{-1/\alpha} \) will be termed symmetric.

**Lemma 5.1.** The symmetric series \( \sum_{j=1}^\infty \varepsilon_j X_j^{-1/\alpha} \) converges a.s. in \( H \) and the log characteristic function of its limit is \( E_{x,Y_1}^{f(x,y)} \), \( \forall x \in H \), where \( B(a) \triangleq \int_0^\infty a(\cos(r)-1) \frac{dr}{r^{1+a}}. \)

**Proof.** The arguments needed are similar to those of theorem 4.8, but easier in the symmetric case. For each \( x \in H \),

\[
\log E e \sum_{j=1}^n \varepsilon_j X_j^{-1/\alpha} = \sum_{j=1}^n \log E e^{\varepsilon_j X_j^{-1/\alpha}} = \sum_{j=1}^n \log E e^{\varepsilon_j X_j^{-1/\alpha}} e^{-1/\alpha} \frac{dr}{r^{1/\alpha}}
\]

\[
= a E \int_0^\infty (e^{-1/\alpha} -1) I(\|X_1\| < ra_n^{1/\alpha}) (x, X_1) \frac{dr}{r^{1/\alpha}}
\]

\[
= a E \int_0^\infty (\cos(r)-1) I(\|X_1\| < ra_n^{1/\alpha}) (x, X_1) \frac{dr}{r^{1/\alpha}}
\]

\[
= a \int_0^\infty (\cos(r)-1) \frac{dr}{r^{1+a}} E (x, X_1) \frac{\alpha}{\alpha}
\]

From ([3], corollary 2.1), the limit in (5.2) is the characteristic.
function of a (symmetric) stable law on \( H \). Since the sums
\[
\sum_{j=1}^{K_n} x_j^{-1/\alpha}
\]
are independent and symmetric, we have from (12), theorem 5.3(1)) that
\[
\sum_{j=1}^{K_n} x_j^{-1/\alpha}
\]
converges a.s. in \( H \). Since eventually a.s. \( K_n+1 \leq K_n+1 \) as \( n \to \infty \), we conclude \( \sum_{j=1}^{K_n} x_j^{-1/\alpha} \)
converges a.s. in \( H \). \( \square \)

Several series may represent the same stable law.

**Theorem 5.2.** If \( \sum_{i=1}^{\infty} x_i^\alpha < \infty \) then for every \( x \in H \),
\[
E|(x,x_1)_\alpha|^\alpha = E|x_1^\alpha E(x,x_1^*)^\alpha\]
where \( x_1^* \) is distributed on \( S \) according to the measure:
\[
P(x_1^* \in A) = EI(\frac{x_1^*}{||X_1^*||} \in A)\frac{X_1^*}{E|X_1^*|\alpha}
\]

**Proof.** For every \( x \in H \),
\[
E'(x,x_1)_\alpha = E,(x, \frac{x_1}{||X_1||})_{\alpha} ||x_1||^\alpha
\]
\[
= E|X_1^*|\alpha E'(x,x_1^*)^\alpha \tag{1} \]

As an example of the above, every symmetric stable law on \( H \) has a construction \( \sum_{j=1}^{\infty} Z_j x_j^{-1/\alpha}/E(|Z_1^*|\alpha)^{1/\alpha} \) in terms of an independent sequence \( Z \) of i.i.d. standard normal r.v.'s. Conditional on the sequences \( \Gamma \) and \( X \) the symmetric stable is Gaussian. That is, symmetric stable laws are particular mixtures of Gaussian laws with zero means and differing covariance kernels. The latter will not in general differ only by scale, though this is necessarily true for \( H = R_1 \).

Let \( \{r_j, j \geq 1\} \) be i.i.d. taking values in a measurable space with measurable sets generically denoted \( A \). Suppose \( \tau, \tau', X, \tau' \) are mutually independent, where the latter three sequences are as in section 5. Define

\[
X(\tau) \triangleq \sum_{j=1}^{\infty} \mathbb{I}(\tau_j \in \tau) X_j \tau_j^{-1/\alpha}, \forall \tau.
\]

**Theorem 6.2.** The series (6.1) is a.s. convergent for each \( \tau \), is jointly symmetric stable for finitely many \( \tau \), and \( X(\tau_1), \ldots, X(\tau_n) \) are for each \( n \geq 1 \) mutually independent if \( A_1, \ldots, A_n \) are mutually disjoint.

**Proof.** For each \( n \geq 1 \), \( x \in H \), real numbers \( r_1, \ldots, r_n \), and measurable sets \( A_1, \ldots, A_n \),

\[
\log E e^{i(x, \sum_{k=1}^{n} r_k X(A_k))} = \log E e^{i \sum_{j=1}^{\infty} \sum_{k=1}^{n} r_k \mathbb{I}(\tau_j \in A_k)} (x, X_j) \tau_j^{-1/\alpha}.
\]

(5.1)

If \( A_1, \ldots, A_n \) are mutually disjoint then

\[
E \sum_{k=1}^{n} r_k \mathbb{I}(\tau_1 \in A_k)^{\beta} = \sum_{k=1}^{n} r_k^{\beta} \mathbb{P}(\tau_1 \in A_k).
\]

(6.4)
Remark. The simplicity of this construction is intuitive, as is the way in which i-dependence, dimensional structure, and functional dependence are identified with mutually independent coefficient sequences \( -\frac{1}{\alpha}, X, Y \).

Remark. Schilder [8] and Kuelbs [3] have explored a representation of multidimensional symmetric stable r.v. by means of a stochastic integral with respect to a one-dimensional stable independent increments process. Theorem (4.8) and Lemma (5.1) sharpen and extend such representations by connecting them with the Ferguson-Klass representation, making explicit the choice of coefficients required to obtain each stable law \( \alpha \), and establishing \( H \) convergence of the indicated series.

Remark. Suppose \( K \cdot 1 \) and \( Y_k = \sum_{1}^{\infty} \xi_{kj}^{k} - \frac{1}{\alpha}, 1 \leq j \leq K \), are independently constructed (as per \( (5.1) \)) symmetric stable r.v. taking values in \( K \). Then for an arbitrary choice of real numbers \( r_1, \ldots, r_K \), the sum \( \sum_{1}^{K} r_k \xi_{kj}^{k} \) is representable \( \sum_{1}^{\infty} \xi_{kj}^{k} - \frac{1}{\alpha} \) where \( \xi_{kj}^{k} \) are i.i.d. and \( \xi_{kj}^{k} \) are equiprobable random selection from \( K \). This uses the property (discussed in Section 3) of \( K \) Poisson processes run simultaneously.

**Included the non-symmetric stable laws.**

Basically, we seek to construct the stable analogues of Gaussian stationary random functions having a harmonic decomposition. The characteristic function of such a Gaussian random function involves

$$E \sum_{k=1}^{n} r_k e^{i(i_{1}, t_{k_{o}})^{2}}$$

where $t$ is generic for a point of the domain, and $(i_{1}, )_{o}$ is a random linear function on the domain. The stable analogues of these Gaussian random functions have characteristic functions that employ an $\alpha$-power in this integral instead of the 2, but are otherwise the same. Define $\omega t$,

$$(7.1) \quad X(t) = \sum_{j} r_j \cos((i_{j}, t) + \omega_j) X_j \xi_j^{-1/\alpha},$$

where $\omega$ are i.i.d., $\xi$ are i.i.d. uniforms on $[-\pi, \pi]$, $(\xi, X, \omega)$ are as in section 6, and $\Lambda, \Theta, \varepsilon, X, \tau$ are mutually independent sequences. The series (7.1) is a.s. convergent in $H$ for each $t$ by lemma 5.1. The random function $X(t)$ is clearly stationary because $\Theta$ are uniform on $[-\pi, \pi]$, but this will also be a simple consequence of the form of the characteristic function which we now compute.

$$i(x, \sum_{k=1}^{n} r_k X(t_k))$$

$$(7.2) \quad \log E e^{-i(x, \sum_{k=1}^{n} r_k X(t_k))}$$

$$= \log E e^{-i \sum_{j=1}^{\infty} r_j \cos((i_j, t) + \omega_j) X_j \xi_j^{-1/\alpha}}$$

$$= \log E \sum_{k=1}^{n} r_k \cos((i_{k}, t_{k_{o}} + \omega_{k}) \xi_{k}^{-1/\alpha})$$

$$= B(\alpha) E \left| (x, X_{\omega}) \right|^{2} E \sum_{k=1}^{n} r_k \cos((i_{k}, t_{k_{o}} + \omega_{k}) \xi_{k}^{-1/\alpha},$$

16
The final term in the right side of (7.2) reduces as follows, with

\[ z^{\frac{1}{n}} \sum_{k=1}^{n} e^{i\langle \xi_{k}, t_{h} \rangle} \]

\[ E_{1}^{\alpha} \sum_{k=1}^{n} r_{k} \cos(\langle \xi_{k}^{*}, t_{h} \rangle + \Theta_{k}) \]

\[ = E_{1}^{\alpha} z^{i\Theta_{1}} + z^{-i\Theta_{1}} \]

(7.3)

\[ = E_{1}^{\alpha} z^{i\Theta_{1} - 2i\Theta_{1}} + z^{-1} z^{i\Theta_{1}} \]

\[ = E_{1}^{\alpha} z^{i\Theta_{1} - 2i\Theta_{1}} \]

where

\[ C(\alpha) = \int_{-\infty}^{\infty} \frac{1 + e^{i\alpha \psi}}{1 + e^{i\psi}} d\psi \]

for all real \( \psi \). We have therefore proved,

**Theorem 7.4.** The random function defined by (7.1) converges a.s. in \( H \) for each \( t \), and has log characteristic function

\[ 2^{-\alpha} B(\alpha) C(\alpha) E_{1}^{\alpha} \sum_{k=1}^{n} r_{k} e^{i\langle \xi_{k}, t_{h} \rangle} \]

for all \( n \geq 1, r_{1}, \ldots, r_{n}, t_{1}, \ldots, t_{n} \).

**Corollary 7.5.** The random function (7.1) is non-ergodic for each \( \alpha < 2 \).

**Proof.** By using (7.3) the construction (7.1) remains valid if \( \xi_{j} \) are replaced by \( Z_{j} / (E_{1}^{\alpha} Z_{1}^{\alpha})^{1/\alpha} \), \( j \geq 1 \), where \( Z \) is an independent i.i.d. standard normal sequence. Conditional on the sequences \( A, X, \gamma \), the
process (7.1) is a.s. stationary Gaussian with discrete spectrum, therefore conditionally non-ergodic a.s.

Infinitely divisible laws, of which the operator stable laws are a special case with particularly interesting structure, are treated in Part II. In brief, this is what happens: A construction of infinitely divisible random vectors is given by \( \Sigma \{ X_j H(T^{-1}_j, X_j) - \gamma_j \} \), in which the real function \( H \) is monotone decreasing and positive for each value \( X_j \), and is determined from the Lévy measure. A construction of full operator stable random vectors in a finite dimensional real vector space \( \mathbb{R}^d \) is \( \Sigma \{ A(T^{-1}_j) X_j - \gamma_j \} \), in which the vectors \( \gamma \) are non-stochastic centerings, \( \{ A(t) = \exp(\text{Blog} t), t > 0 \} \) is the group of linear transformations figuring in the definition of operator stability (e.g. Sharpe [9]), and the vectors \( X \) are i.i.d. from a probability measure (a factor of the Lévy measure) on a set of generators of the subgroups induced by \( A \). The methods of sections 4 and 5 carry over, as will now be indicated. If \( X \) is any i.i.d. sequence in \( \mathbb{R}^d \), and \( X \) is independent of \( T \), then

\[
\forall x \in \mathbb{R}^d, n > 1,
\]

\[
\log_e \mathbb{E} e^{i(x, \Xi_n A(T^{-1}_j) X_j)} = \int_{-1}^{\infty} \mathbb{E}(e^{i(x, A(t) \Xi_n) - 1}) \frac{dr}{t^2} .
\]

As usual, the symmetric case is simplest. If we examine Sharpe's Theorem 5, we discover that the limit of (8.1) is precisely the form taken by the operator stable in this case, provided we choose for the distribution of \( X_j \) the probability measure figuring in Sharpe's representation of the Lévy measure as a mixture, this measure being placed on (Sharpe's notation) generators \( \mathcal{B} \) characterized by \( s X_0^t B_{s^{-1}} : s > 0 \). Arguing as in section 5, we conclude \( \Sigma \{ A(T^{-1}_j) X_j \} \) converges a.s. in \( \mathbb{R}^d \) and has the log-characteristic function which is the limit of (8.1).

P. Lévy has anticipated the series constructions of one dimensional stable r.v. with $\alpha < 2$. For the case of a positive stable with $\alpha < 1$, up to scale and location, this construction is $\sum_{j=1}^{\infty} r_j^{-1/\alpha}$, with $\{\Gamma_j, j > 1\}$ being the arrival times of a Poisson process (on $\mathbb{R}^+$) having unit intensity function. Lévy writes the series in the form $\sum \sum_{x} U_x$, where

\begin{equation}
\{U_x, x > 0\} \text{ are independent r.v. and }
\end{equation}

\begin{equation}
P(U_x = x) = \frac{adx}{x^{1+\alpha}} = 1 - P(U_x = 0).
\end{equation}

Here is my abstract of the key parts of Lévy's (1935) arguments for the above case:

\begin{equation}
\left[ \int_{x_0}^{\infty} \frac{adx}{x^{1+\alpha}} = x_0^{-\alpha} < \infty \right] \Rightarrow \left[ \{U_x: U_x \neq 0, x > x_0\} \text{ is finite for } x_0 > 0 \right],
\end{equation}

and also,

\begin{equation}
\left[ \int_{0}^{x_0} \frac{adx}{x^\alpha} = \frac{x^{1-\alpha}}{1-\alpha} x_0^{(1-\alpha)} + 0 \right] \Rightarrow \left[ E \sum_{x} U_x = 0 \right] \text{ (as } x_0 \downarrow 0).
\end{equation}

Therefore, for arbitrary $c_1, c_2 > 0$ (defining $c_3 = c_1 + c_2$ and taking independent copies),

20
\[(9.5) \quad c_1 \sum_x U_x^{(1)} + c_2 \sum_x U_x^{(2)} \overset{\text{Dist.}}{=} \sum_x Y_x^{(1)} + \sum_x Y_x^{(2)} \]

\[
\begin{align*}
\text{Dist.} & \quad \sum_x Y_x \\
\text{Dist.} & \quad c_3 \sum_x U_x \quad (\Rightarrow \text{stable}),
\end{align*}
\]

where \(\{Y_x^{(k)}, x > 0\}\) have respective intensities \(c_k^3 \alpha \frac{dx}{x^{1+\alpha}}\), \(k = 1, 2, 3\), and are independent for \(k = 1, 2\).

The above arguments do yield a proof of the representation if we apply them to the independent sub-sums \(\sum_{b_n}^{b_{n+1}} \{U_x : x \in [b_n, b_n]\}\), \(n \geq 1\), where \(b_n^{\alpha} = \log n\). This is essentially the argument of Ferguson-Klass (1972). The particular choice of \(b_n\), \(n \geq 1\) is one which ensures that eventually as \(n \to \infty\) each sub-sum contains at most one summand, so it really is (almost) as though one could add independent \(U_x\) one at a time toward \(x \to 0\). A quite different justification is to interpret \(\sum_x U_x\) as a generalized process driven by "white noise" \(\{U_x, x > 0\}\).

Lévy's observations are easily overlooked. Ferguson-Klass, Vervaat (1979), LePage-Woodroofe-Zinn (1979) (in manuscript form), rediscover the Lévy construction as byproducts of the following independent pursuits respectively: (F-K) representing the positive non-Gaussian part of an independent increments random function as the sum of its ordered jumps.

(V)-examining a shot-noise associated with the asymptotic behavior of the solution of a stochastic difference equation as time is increased.

(L-W-Z)-studying the limit behavior of the normalized order statistics.
from a distribution attracted to a stable. Resnick (1976) reconciles the Ferguson-Klass construction with the Ito representation, meaning by the latter Ito's generalization of Lévy's stochastic integral construction by a Poisson random measure.

Acknowledgement. The estimate (4.6) was suggested by J. Zinn. Helpful discussions were also held with V. Mandrekar, M. Woodroofe, and M. Steele.
