Electrochemistry and Spectroelectrochemistry of Mononuclear, Binuclear and Tetranuclear Zinc Neopentoxysubstituted Phthalocyanines are presented. The Binuclear and Tetranuclear species show two oxidation waves to the radical cation indicating the existence of stable mixed valence, half-oxidized species. The electronic spectra of the half- and fully oxidized species are presented and discussed. Nernstian analysis shows that pairs of phthalocyanine rings are oxidized simultaneously in the tetranuclear species, via a one-electron oxidation pathway.

Abstract

The electrochemistry and spectroelectrochemistry of mononuclear, binuclear and tetranuclear zinc neopentoxy-substituted phthalocyanines are presented. The binuclear and tetranuclear species show two oxidation waves to the radical cation indicating the existence of stable mixed valence, half-oxidized species. The electronic spectra of the half- and fully oxidized species are presented and discussed. Nernstian analysis shows that pairs of phthalocyanine rings are oxidized simultaneously in the tetranuclear species, via a one-electron oxidation pathway.
INTRODUCTION

Certain binuclear porphyrins and phthalocyanines (Pc) containing two metal centers have recently been found to produce species with mixed metal valencies. For example electrochemical studies of binary cofacial dicobalt porphyrin complexes show that the cobalt centers are oxidized or reduced separately in two different mono-electronic steps to give mixed valence compounds containing \([\text{Co}^{11}\text{Co}^{11}]\) and \([\text{Co}^{1}\text{Co}^{11}]\) metal centers respectively. Binuclear cobalt phthalocyanines either linked by a common benzene ring or a 1,8-naphthalene bridge, form mixed valence metal centers \([\text{Co}^{1+}\text{Co}^{1}]\) upon electrochemical reduction. Collman et al have reported stable mixed valence ruthenium \([\text{Ru}^{11}\text{Ru}^{11}]\) and \([\text{Os}^{11}\text{Os}^{11}]\) porphyrins.

Bis(phthalocyaninato)lanthanide(III) derivatives of the structure \([\text{Pc}(-1)\text{Ln}^{III}\text{Pc}(-2)]\), in which a trivalent lanthanide cation is sandwiched between a phthalocyanine and a one-electron oxidized phthalocyanine, have been prepared. These complexes undergo reversible one-electron chemical and electrochemical oxidations to the doubly oxidized \(\pi\)-cation species \([(\text{Pc}(-1))_{2}\text{Ln}(\text{III})]^{+}\), or reduction to \([(\text{Pc}(-2))_{2}\text{Ln}(\text{III})]^{-}\). Similarly, binuclear mixed valence porphyrin species, in which one of the rings is oxidized to its \(\pi\)-cation radical have also been reported for some trivalent lanthanide sandwich-like bis-porphyrins; while a cerium(IV) bis(porphyrin) has been found to form a mixed valence ring oxidized species by chemical or electrochemical oxidation. A planar laterally bridged binuclear (metal-free or zinc) porphyrin has been observed to undergo four consecutive one-electron reductions, although no mixed valence species were reported. A \([(\text{OEP})\text{Nb}]_{2}\text{Os}\) binuclear complex has been reported to undergo stepwise one-electron oxidation to a mixed...
valence ring-oxidized species by electrochemical oxidation.\textsuperscript{17} Oligomeric silicon phthalocyanines show stepwise oxidation or reduction of the phthalocyanine rings\textsuperscript{18,19}. Our interest in the generation of mixed valence phthalocyanine species prompted us to investigate the electrochemistry and spectroelectrochemistry of binuclear and tetranuclear zinc phthalocyanines.

Recently we reported the electrochemistry and spectroelectrochemistry of a series of binuclear dicobalt phthalocyanines linked by bridges of one, two, four or five atoms,\textsuperscript{20} and of a tetranuclear phthalocyanine.\textsuperscript{21} No splitting of the redox couples was observed, the redox processes occurring via two one-electron transfers, at the same potential, at each phthalocyanine unit. In contrast, the analogous zinc derivatives of the five atom linked 'clamshell' (1) and the tetranuclear phthalocyanine (2) show splitting of the first oxidation couple, and permit the observation of mixed valence ring oxidized species. This is the first report of the spectroscopic characteristics of mixed valence ring oxidized species in binuclear dimetallic phthalocyanines.

Electrochemical data for mononuclear ZnPc species have been reported in the literature.\textsuperscript{22-26} ZnPc undergoes oxidation at the ring rather than at the metal center, resulting in the formation of a phthalocyanine n-cation radical. This has also been prepared by chemical oxidation using thionyl chloride, bromine\textsuperscript{7} or iron(III) perchlorate\textsuperscript{27}. Recently Nyokong \textit{et al.}\textsuperscript{26,28} have reported the optical and MCD spectra of the cation radical, $[\text{ZnPc}(-1)]^+$. Octacyanosubstituted zinc phthalocyanine, (CN)$_8$PcZn, exhibits four reversible, one-electron reduction steps which correspond to the formation of the mono-, di-, tri-, and tetra-anion.\textsuperscript{25,29}
EXPERIMENTAL

Materials:

Tetrabutylammonium perchlorate (TBAP, Kodak) was recrystallized from absolute ethanol and dried in a vacuum oven at 60°C for two days. 1,2-Dichlorobenzene (DCB, Aldrich, Gold Label), and N,N-dimethylformamide (DMF, Aldrich, anhydrous Gold Label) were used as supplied.

Methods:

Electronic spectra were recorded with a Hitachi-Perkin Elmer Microprocessor model 340 spectrometer. Cyclic and differential pulse voltammetry were performed with a Princeton Applied Research (PARC) model 174A Polarographic Analyzer coupled to a PARC model 175 Universal programmer. Electrochemical data were recorded under an atmosphere of argon, or nitrogen, using a conventional three electrode cell. A platinum disk described by the cross-sectional area of a 27-gauge wire (area \(10^{-3}\) cm²), sealed in glass, was used as the working electrode, a platinum wire served as the counter electrode, and a Ag/AgCl reference electrode (-0.045V vs SCE) (in sat. KCl separated by a frit) corrected for junction potentials by being referenced internally to the ferrocenium/ferrocene (Fc⁺/Fc) couple (0.31 V vs SCE). All DMF solutions were prepared and measurements made under an atmosphere of argon, within a Vacuum Atmospheres Drilab. The DCB solutions were prepared in air, degassed by purging with N₂ gas and the measurements were carried out in a glove bag filled with an atmosphere of dry N₂.

The stability of the Ag/AgCl/Cl⁻ electrode was checked using a solution of ferrocene in DCB; it was stable for at least two days. In various experiments involving DMF solutions, the Fc⁺/Fc couple was seen to lie in the range +0.35 - 0.45V vs Ag/AgCl/Cl⁻, due to variations in junction potentials. In DCB, the Fc⁺/Fc couple was observed at
approximately 0.6V vs Ag/AgCl/Cl⁻.

Spectroelectrochemical measurements were made with a 0.1 cm path length optically transparent electrode cell utilizing a Pt minigrid, in conjunction with the Hitachi Perkin-Elmer spectrometer. A platinum-flag, used as the counter electrode, was separated from the working compartment by a medium glass frit. Controlled potential electrolysis was carried out using a PARC model 173/179 potentiostat. Solutions were continously purged with argon throughout the experiment. Solutions for electro-chemistry or spectroelectrochemistry contained 0.1-0.2M or 0.3M TBAP, respectively, as the supporting electrolyte.

Electron spin resonance data were obtained using a Varian model E4 spectrometer calibrated with diphenylpicrylhydrazide. Esr spectra of electrochemically generated [ZnTrNPc]₄ species were obtained by bulk electrolysis of a solution (degassed by freeze-pump-thaw cycles) under an atmosphere of nitrogen in the dry box, and transferring the species to sealable esr tubes. The electronic spectra of these solutions were also recorded. The bulk electrolysis cell consisted of a platinum plate working electrode, a platinum flag counter electrode, and a silver wire quasi-reference electrode. Counter and reference electrodes were separated from the working compartment by medium glass frits.

Solutions for aggregation studies were prepared by dilution of a freshly prepared stock solution of phthalocyanine. Spectra were recorded immediately after each dilution and solutions were shielded from room light to minimise any photochemical decomposition of phthalocyanine.

**Synthesis:**

The synthetic procedures give rise to mixtures of isomers in which the neopentoxy groups are randomly distributed about the phthalocyanine ring. For ease of description we describe the syntheses of specifically
defined isomers. 2,9,16,23-Tetraneopentoxyphthalocyaninato-zinc (ZnTNPc) and the metal free phthalocyanines 1,3-bis-2'-(9,16,23-trineopentoxyphthalocyaninoxy)-2-ethyl-2-methylpropane (EtMeO(5)[H2TrNPc]2) and tetrakis(((9,16,23-trineopentoxyphthalocyanin-2-yl)oxy)methyl)-methane ([H2TrNPc]4) were prepared according to literature methods21,34.

1,3-bis-2'-(9,16,23-trineopentoxyphthalocyaninoxy-zinc)-2-ethyl-2-methylpropane (EtMeO(5)[ZnTrNPc]2): A mixture of EtMeO(5)[ZnTrNPc]2 (32 mg, 0.019 mmole), zinc acetate (125 mg, 0.68 mmole), 2-methoxy-ethanol (5ml) and toluene (10ml) was heated at 120°C for 16 hours under an argon atmosphere. The solution was cooled and the product purified by flash chromatography using a column packed with silica gel following direct application of the mixture to the column. The column was eluted with toluene and the bluish green band collected. The solid isolated on evaporation of toluene was washed with methanol to give a bluish green product (26.9 mg; 79% yield). MS, m/e: 1786.7 M+ (100%).

Anal. Calcd. for C106H108Ni6O8Zn2: C, 67.22; H, 5.75; N, 12.54; Zn, 7.32. Found: C, 68.1; H, 6.2; N, 12.9; Zn, 7.4.

Tetrakis(((9,16,23-trineopentoxyphthalocyanin-2-yl)oxy-zinc)methyl)-methane ([ZnTrNPc]4): A mixture of [H2TrNPc]4 (38 mg, 0.012 mmole), Zn(OAc)2 (94.3 mg, 0.51 mmole), 2-methoxyethanol (4ml), and toluene (8ml) was heated at 120°C for 18 hours under an argon atmosphere. The solution was cooled and the product purified by flash chromatography using a column packed with silica gel following direct application of the mixture to the column. The mixture was eluted with toluene and the bluish green band collected. The solvent was evaporated to yield a dark blue solid (33 mg, 80% yield). MS, m/e: 3473.2 M+ (100%). Anal. Calcd. for C193H188Ni6O16Zn4: C, 66.74; H, 5.46; N, 12.91; Zn, 7.53. Found: C, 67.6; H, 6.1; N, 12.0; Zn 7.0. Some analyses are not as close to theory as one would prefer; there
are well known difficulties in analysing phthalocyanines. However the mass spectra provide additional confirmatory evidence for molecular formulae.

RESULTS AND DISCUSSION

Aggregation Studies

Electrochemical studies of phthalocyanines are usually complicated by aggregation in solution to form dimers and higher aggregates. For example, in the cyclic voltammograms (CV) of metallooctacyanophthalocyanines the first one-electron reduction consists of overlapping waves due to monomeric and aggregated reactants,\textsuperscript{25,29} while aggregation of the tetranuclear [CoTrNPc]₄ complex in solution causes poorly defined waves.\textsuperscript{21}

When aggregation occurs a band at around 630 nm arises in the electronic spectrum, as a result of the intermolecular interaction (exciton coupling)\textsuperscript{35} between the phthalocyanine units.\textsuperscript{36,37} In binuclear or tetranuclear metallophthalocyanines, intramolecular coupling between the rings also causes a band at around 630 nm.\textsuperscript{21,36} Both ZnTNPc and EtMeO(5)[ZnTrNPc]₂ in DCB solution obey Beer's law up to concentrations of 2x10⁻⁴M and 9.4x10⁻⁵M respectively. Thus there is no significant aggregation in these systems at the concentrations employed in electrochemical studies. Aggregation studies on the corresponding Co systems\textsuperscript{36} show deviation from Beer's law for the Q band at concentrations of an order of magnitude lower than for the zinc system.

The addition of TBAP to EtMeO(5)[ZnTrNPc]₂ in DCB increases the relative intensity of the 680 nm to the 630 nm band. The ratio (As₈₀/As₆₃₀) increases by a constant percentage over an order of magnitude concentration range of the phthalocyanine in DCB (Table I), in the regime where intermolecular aggregation does not occur. Thus TBAP causes a decrease in the intramolecular coupling between the phthalocyanine rings. There is no significant change in the relative intensity of the 680 nm to
the vibrational 614 nm band (A_{614}/A_{680}) in mononuclear ZnTNPc in DCB, upon addition of TBAP at a concentration at which only monomeric ZnTNPc is present, and therefore no formation of aggregates which would have decreased the 680nm absorption while increasing absorption in the 614-630nm region. This is in contrast to the CoTNPc data, where the addition of electrolyte (TBAP) was found to greatly increase the aggregation of the molecules.\textsuperscript{21,36}

**Electrochemistry:**

The cyclic voltammetry of ZnTNPc in DCB or DMF gave two oxidation and two reduction couples within the potential limits of the solvent studied, corresponding to the first and second oxidations and reductions, respectively, of the phthalocyanine ring. In the case of EtMeO(5)[ZnTrNPc]\textsubscript{2} and [ZnTrNPc]\textsubscript{4} in DCB or DMF, three oxidation and two reduction couples were observed. A summary of the half-wave potentials and the peak to peak separation of each wave is given in Table II. In the case of ZnTNPc, the peak at \(\sim 0.0\) V (vs Fc\textsuperscript{+}/Fc), corresponds to the oxidation of the phthalocyanine ligand, forming \([\text{Zn}^{II}\text{TNPc}(-1)]\). Similarly in the binuclear and tetranuclear phthalocyanine cases the double peaks at \(\sim 0.0\) V (vs Fc\textsuperscript{+}/Fc) also correspond to the oxidation of the phthalocyanine ligand. These narrowly separated waves are shown in Fig. 1 together with the CV of the mononuclear phthalocyanine for comparison. Controlled potential electrochemistry (see below) confirms that these two waves arise from the stepwise oxidation of the two phthalocyanine rings, or two pairs of rings, of the same molecule. The separation between these waves increases in DMF solution (150 and 80mV in DMF and DCB respectively for EtMeO(5)[ZnTrNPc]\textsubscript{2} and clearly resolved CV and differential pulse voltammetry (DPV) curves are obtained (Fig.1). Although the anodic to cathodic peak separation is difficult to determine accurately, the estimated values are close to 59 mV
and $i_p$ is proportional to $v^{1/2}$ confirming a diffusion controlled one electron transfer step.

No splitting was observed in the other redox peaks and the potentials of these redox couples are in close agreement for the mononuclear, binuclear and tetranuclear systems. Thus, there is no stabilization of mixed valence anion radical species. Although the half-wave potentials of ZnTNPc in DMF are different from those of ZnPc(Im) (Im = imidazole) and ZnPc(Py) (Py = Pyridine) complexes, the separation between the oxidation and reduction couples is the same. The redox potentials of ZnPc(Im) are about 200 mV more positive than those of ZnTNPc in DMF, possibly a consequence of the difference in the coordinating abilities of the solvent and the axial ligands.

**Spectroelectrochemistry:**

Stepwise controlled potential oxidation of a solution of ZnTNPc in DCB results in the spectroscopic changes shown in Fig. 2a and a change in solution color from bluish green to pink. Isosbestic points are observed at 338, 388, 580 and 708 nm. Spectroscopic data are given in Table III. The final spectrum has a similar appearance to other phthalocyanine π-cation radical species spectra and agrees fairly closely with the absorption spectrum of the [ZnPc$\cdot\cdot\cdot$] species reported by Nyokong et al.

The presence of a split electrochemical wave for the oxidation process in the bi- and tetranuclear systems, implies the existence of a mixed valence species (MVS), whose spectrum may be obtained by oxidizing the species stepwise through this pair of electrochemical waves. Such data for a solution of [ZnTNPc]$^+$ in DCB are shown in Fig. 2b. Similar spectroscopic changes were observed following the stepwise oxidation of EthMeO(0.5)[ZnTnPc]$^2$ along its first and second oxidation waves. For the
tetranuclear species, isosbestic points occur in the first stage of oxidation, to the MVS, at 328, 384, 580 and 720nm, shifting to 328, 380, 580 and 714nm in the second stage oxidation. The final spectra (1-electron/phthalocyanine ring oxidized) of both the binuclear and tetranuclear species are similar to that of the oxidized mononuclear zinc phthalocyanine except for the absence of a broad band around 400 nm (see Table III).

A graphical analysis can be used to determine the number of species in solution from the spectroscopic data. If the absorbance value of a particular solution, \( j \), at a specific wavelength \( i \), is denoted by \( A_{ij} \), a plot of \( A_{ij} - A_{ij'} \) for a series of solutions, \( j' \), at wavelength \( i \) vs the corresponding difference \( A_{ij'} - A_{ij''} \) at another wavelength \( i' \) will give a straight line passing through the origin for each \( i' \) if only two species exist in solution. When the spectroelectrochemical data associated with ZnTNPc in DCB (Fig. 2a) are analyzed in this way an excellent straight line passing through the origin is obtained (Fig 3a). In contrast, the spectroelectrochemical data for the binuclear and tetranuclear systems fail to give a good straight line with the above analysis (shown for (2) in Fig. 3b), even though the presence of isosbestic points implies that the data are good; this suggests that more than two species are present in solution. In these cases the test for three species in solution is positive since plots of \( (A_{ij} - A_{ij'})/(A_{ij} - A_{ij''}) \) vs \( (A_{ij'} - A_{ij''})/(A_{ij} - A_{ij''}) \) give a straight line (see Fig. 3c), where 1, 2, and 3 are different wave-lengths and \( j' \) is a specific solution.

A nernstian plot of the spectroelectrochemical data for ZnTNPc in DCB over the first oxidation wave gives a slope of 58(±1)mV, and an intercept at \( E_{1/2} \), in concordance with a one-electron process.

Nernstian plots of the spectroelectrochemical data over the first and
second oxidation waves of EtMeO(5)[ZnTrNPe]₂ and [ZnTrNPe]₄ are obtained by considering the oxidation of initial phthalocyanine (SS) to MVS and oxidation of MVS to the final product (OxOx) as two independent electrochemical steps. Assuming the potentials shown in Table I, the distribution of SS, MVS and OxOx is shown for (2) in JCB in Fig. 4. Below about 0.53V, and above about 0.6V there are essentially only two species in equilibrium. In these regions it is a reasonable approximation to plot log([MVS]/[SS]) and log([OxOx]/[MVS]), each, against potential to obtain conventional two species nernstian plots. The results are shown in Fig. 5. The spectrscopically derived half-wave potentials are 0.50 and 0.62V vs Ag/AgCl/Cl⁻ compared with the electrochemically derived 0.52 and 0.63V respectively (Table II). The slope for the latter plot is in perfect agreement with expectation, while that of the former (with a lower regression coefficient) is slightly high. Nevertheless the data confirm that, mechanistically, these individual couples are one-electron processes. The nernstian slopes (data not shown) for the dinuclear system (1) are 69 and 55 mV respectively.

A coulometric study of the double oxidation wave of the dinuclear (1) species yields 2.08 electrons/molecule. Stopping the coulometry experiment in the centre of the double wave yielded approximately 1 electron/molecule though the two waves are too close together to obtain this number accurately.

Thus the reactions corresponding to the split oxidation waves in the voltammograms are one electron processes. The observation of two sets of well defined isosbestic points, the splitting of the oxidation wave into two components in the cyclic voltammograms, and the coulometric and nernstian analyzes clearly indicate that for the dinuclear zinc complex, oxidation of the phthalocyanine rings of each molecule occurs in two
one-electron steps, while in the case of the tetranuclear system, oxidation occurs in two steps, each involving the simultaneous one-electron oxidation of a pair of phthalocyanine rings. Therefore the final oxidized product is formed via an intermediate species which contains ligands of mixed valencies.

Chemical oxidation of ZnTNPc to its π-cation radical can be achieved using either silver perchlorate or bromine, though in the former case, it appears impossible to achieve complete oxidation even with a very large excess of silver(I). On the other hand, bromine (in CCl₄) can completely oxidize ZnTNPc to its cation radical when a two fold excess is used. If a 2-fold equivalent excess of bromine is added to [ZnTrNPc]₄, the MVS species is formed. The electronic spectrum of this solution does not show bands at 388 and 730 nm and only a weak band at 1080 nm, in agreement with the calculated spectrum of the MVS.

Electronic spectra:

The electronic spectra of the bi- and tetranuclear zinc (OxOx) cation radical species differ from that of the mononuclear radical cation (compare Figs. 2a and 2b), having a peak near 380 nm rather than broad absorption in the 380-440 nm range. Minor et al.48 first rationalized the spectra of phthalocyanine radical cations, while, more recently, Nyokong et al.28 assigned the various transitions of [ZnPc]⁺ through analysis of its absorption and magnetic circular dichroism spectra. On these bases, the absorption band near 680-725 nm in all the OxOx radical cation species here discussed is assigned as the π-π* Q band, and the 380 and 330 nm absorption as the Soret (B band) π-π* and N → π transitions as discussed in depth elsewhere.28 The bands near 520 and 860 nm are assigned as π-π transitions to the Au HOMO, also in accordance with Nyokong et al.28

MVS electronic spectra: The absorption spectrum of the tetranuclear
(2) MVS was calculated by deconvolution of the spectro-electrochemical data, using the distribution shown in Fig. 4. For maximum accuracy, the spectrum obtained at approximately the mid-point potential of the two waves, where the concentration of the MVS is at a maximum, was deconvoluted. The resulting MVS spectrum is shown in Fig. 6. When superimposed onto Fig. 2b, the MVS spectrum (normalised to the same concentration) crosses through the isosbestic points, as is required. Similar data were obtained using the binuclear species.

The calculated spectrum of the MVS does not show bands at 388 and 730 nm whereas it exhibits all the other bands which appear in the fully oxidized cation (see Table III). In the near IR region the band at 1080 nm is very weak for the MVS but appears as a relatively strong (broad) band for the doubly oxidized species.

The existence of the MVS implies some degree of electronic coupling between the un-oxidised and oxidised rings. In the absence of such coupling, the electronic spectrum would be the simple mean of the oxidised and un-oxidised species. Thus the difference between the observed MVS electronic spectrum and the calculated mean spectrum of the oxidised and un-oxidised ring, is a measure of the spectroscopic consequences of this electronic coupling. This difference spectrum is shown for species (2) in Fig. 6. There are small shifts observed in the Q and Soret regions and also a small shift in the characteristic radical cation band near 520 nm. This provides further evidence of the unique character of the MVS species.

The band at 1080 nm is a candidate for an inter-valence (IT) transition given its typical IT characteristics being broad and in the near infrared region. However it grows stronger after the mid-point of the spectro-electrochemical experiments where the concentration of the MVS species must be declining. It is also present in the mononuclear
[ZnTNPc(-1)]+. We conclude therefore that it is a hitherto previously unassigned \( \pi-\pi \) transition of the radical cation. The anticipated IT band must be obscured by the strong and complex \( \pi \)-absorption of this MVS species. A band also appears in the near infrared region, at \( \sim 1000 \text{nm} \), upon the one-electron ring-oxidation of the mixed valence lanthanide diphthalocyanine compounds, i.e. when \([(\text{Pc}(-1))_2\text{Ln}]^+ \) is formed.\(^{10}\) Bands at \( \sim 1000 \text{nm} \) have been reported previously for LiPc(-1),\(^{44b}\) ClMgPc(-1), NO\(_2\)CuPc(-1) and HPc(-1).\(^{44a}\)

The Soret region of the MVS is more symmetric than that of the fully oxidized species, presumably with both the B and N bands lying under the 340nm band envelope.

**Electron Spin Resonance Data:**

The EPR spectrum of a chemically oxidized solution of ZnTNPc in DCB recorded at 77 K gave an isotropic \( g \) value of 2.001(1) with a peak to peak separation of 4G, consistent with an unpaired electron delocalized over the organic fragment. No hyperfine structure was observed on this signal. In contrast, Myers et al.\(^{17}\) found earlier that the oxidation of unsubstituted ZnPc gave a diamagnetic complex which was esr silent and therefore proposed a dimeric radical structure. In ZnTNPc the bulky substituents may prevent the \( \pi \)-clouds of the oxidized cation radical species from getting sufficiently close together. In addition, it was reported that Zn(tetra-4-t-buty]Pc)\(^{50}\), and LZNpC (L = Im or Py)\(^{26}\) on oxidation gave an esr signal characteristic of an organic free radical.

The absorption and esr spectra were recorded during stepwise oxidation of \([\text{ZnTNPc}])\(^4\) in DCB following the first and second oxidation waves. On oxidation across the first wave, there is observed a \( \pi \)-cation radical esr signal whose intensity increases in parallel with the increase in absorbance at 520nm. The signal intensity reaches a maximum when the
appearance of the 388nm band heralds the maximum formation of the MVS. Further oxidation to the fully oxidized species, resulted in a decrease in the ESR signal intensity to a final value of about 50% that of the maximum intensity. Re-reduction of the solution via the MVS, gave an initial increase in the ESR intensity, followed by a decrease to zero upon formation of the initial species.

The MVS of [ZnTrNPc]₄ is a biradical cation which evidently has small or negligible interaction between the two electrons, as for example observed with Ru(2,2'-bipyridine)₃⁺ obtained through two electron reduction of the [Ru(2,2'-bipyridine)₃]²⁺ cation. On further oxidation the electrons in the other pair of ligands interact with the previously oxidized pair which causes the ESR signal intensity to decrease. Thus in the fully oxidized species there is significant interaction between the four oxidized ligands, but it is not strong enough to relax the ESR signal completely.

In contrast, oxidation of the binuclear porphyrin complex [(OEP)Nb]²⁺, beyond the second oxidation wave resulted in the complete disappearance of the free radical ESR signal. One-electron ring-oxidation of the neutral MV lanthanide diphthalocyanine sandwich complexes also results in the loss of the free radical signals.

The g values for the MVS and OxOx [ZnTrNPc]₄ species are equal, at 2.001, and their peak to peak separations are similar, typical for a n-cation phthalocyanine radical species. The g values for the species [1,ZnPc(-1)]⁺, where L = Im, Py or CN⁻ lie between 2.0055 and 2.0068, while g values close to 2.00 are reported for a wide range of phthalocyanine radical cations.
Conclusions:

The electrochemical and spectroelectrochemical data show that the oxidation of phthalocyanine ligands in EtMeO(5)[ZnTrNPc]2 takes place stepwise by two one-electron processes. In [ZnTrNPc]4, oxidation of the phthalocyanine ligands occurs in two steps in which each step involves two simultaneous and independent one-electron processes. Initially all four phthalocyanine rings are stereochemically equivalent. In the first step two rings are oxidized to form the MVS. This is believed to assume a conformation in which half-oxidized pairs of rings (Pc(-2).Pc(-1)) associate, perhaps to generate a D2d conformation about the central (spiro) carbon atom.

The difference in the redox potentials observed for the SS/MVS and MVS/OxOx couples merits comment. Although splitting of redox peaks was seen for the Co(II)/Co(I) couple of "clamshell" cobalt porphyrins1 so such splitting has been observed for any of the corresponding binuclear Co phthalocyanines2. The electronic coupling between the cobalt atoms is not sufficient to cause an observable splitting and the two units of each molecule oxidize or reduce simultaneously. However, this study shows that binuclear ZnTrNPcs with "clamshell" conformation in solution have significant interaction between the ZnTrNPc units which results in observable splitting of the first oxidation wave. The proposal that the MVS is partially delocalized over the two phthalocyanine rings may explain why the MVS has special stability, but does not explain why the cobalt derivatives should not form a similar species. The explanation may lie in a balance between the relative free energies of axial binding by solvent or supporting electrolyte ions and the MVS electronic coupling. An interposing axial group may prevent the two phthalocyanine halves from moving close enough to form a stable electronically coupled MVS in the
cobalt series, but not in the zinc series.

The existence of these compounds provides a new avenue of research into the study of mixed valence phthalocyanine species, hitherto undeveloped.²,³

REFERENCES

6. The standard oxidation state of the dinegative pentahydraniwmion is referred to as Fe(II) and thus the radical cation of Fe(II) and the radical anion of Fe(III) as Fe(II) and Fe(III) in the literature introduced previously.

46. We thank a referee for pointing out that even when there is no splitting of the multi-electron electrochemical wave, an MVS can exist for entropy reasons, i.e. $SS + OxOx \rightarrow 2MVS$; $K_{\text{com}} = 4$.

48. The ratios $[\text{MVS}]/[\text{SS}]$ and $[\text{OxOx}]/[\text{MVS}]$ are obtained by equating them to the expressions $[A_r - A]/[A - A_0]$ where $A$ is the observed absorbance. The data are shown in Fig. 2b. The $A_0$ and $A_r$ terms correspond appropriately to the initial absorbance (data were used at 680 nm) (SS) and final absorbance at 0.75 V ($OxOx$). For MVS, the spectrum at 0.58 V was assumed to represent 80% MVS (via fig. 4) and the $A_0$ and $A_r$ absorbance values derived therefrom accordingly.
