In this paper, we recover sparse signals from their noisy linear measurements by solving nonlinear differential inclusions, which we call Bregman ISS and Linearized Bregman ISS. We show that under proper conditions, there exists a bias-free and sign-consistent point on their solution paths, which corresponds to a signal that is the unbiased estimate of the true signal and whose entries have the same signs as those of the true signs. Therefore, their solution paths are regularization paths better than the LASSO regularization path, since the points on the latter path are biased. We also show how to efficiently compute their solution paths in both continuous and discretized settings: the full solution paths can be exactly computed piece by piece, and a discretization leads to Linearized Bregman iteration, which is faster and easy to parallelize. Theoretical guarantees such as sign-consistency and minimax optimal $l_2$-error bounds are established in both continuous and discrete settings for specific points on the paths. Early-stopping rules for identifying these points are given. The key treatment relies on the development of differential inequalities for differential inclusions and their discretizations.

1. Introduction. We study two continuous time dynamics Bregman ISS$^1$ and Linearized Bregman ISS, as well as the forward-Euler discretization of the latter, for recovering a sparse unknown signal $\beta^* \in \mathbb{R}^p$ from its noisy linear measurements

$$y = X\beta^* + \epsilon.$$  

Here, $y \in \mathbb{R}^n$ is a measurement vector, $X = [x_1, \ldots, x_p] \in \mathbb{R}^{n \times p}$ is a measurement matrix, and $\epsilon$ is unknown random noise. We allow $n < p$ and assume that $\beta^*$ has $s \leq \min\{n, p\}$ nonzero components. For convenience, let $S = \text{supp}(\beta^*)$ and $T$ be its complement, i.e. $T = \{i : \beta^*_i = 0\}$.

The solution path $\{\rho_t, \beta_t\}_{t \geq 0}$ of Bregman ISS is given by the nonlinear

---

Keywords and phrases: Linearized Bregman, Differential Inclusion, Early Stopping Regularization, Statistical Consistency

$^1$ISS abbreviates Inverse Scale Space, a name adopted from the imaging literature [BOXG05]. There, large-scale image features are recovered before small-scale ones.
In this paper, we recover sparse signals from their noisy linear measurements by solving nonlinear differential inclusions, which we call Bregman ISS and Linearized Bregman ISS. We show that under proper conditions, there exists a bias-free and sign-consistent point on their solution paths, which corresponds to a signal that is the unbiased estimate of the true signal and whose entries have the same signs as those of the true signs. Therefore, their solution paths are regularization paths better than the LASSO regularization path, since the points on the latter path are biased. We also show how to efficiently compute their solution paths in both continuous and discretized settings the full solution paths can be exactly computed piece by piece and a discretization leads to Linearized Bregman iteration, which is faster and easy to parallelize. Theoretical guarantees such as signconsistency and minimax optimal l2-error bounds are established in both continuous and discrete settings for specific points on the paths. Early-stopping rules for identifying these points are given. The key treatment relies on the development of differential inequalities for differential inclusions and their discretizations.
differential inclusions:

\begin{align}
\dot{\rho}_t &= \frac{1}{n} X^T (y - X \beta_t), \\
\rho_t &\in \partial \| \beta_t \|_1,
\end{align}

where \( t \geq 0 \) is time, \( \rho_t \in \mathbb{R}^p \) is assumed to be right continuously differentiable in \( t \), \( \dot{\rho}_t \) is the right derivative of \( \rho_t \), and \( \beta_t \) is assumed to be right continuous. The inclusion condition (1.2b) restricts \( \rho_t \) to a subgradient of \( \ell_1 \)-norm at \( \beta_t \), \( t \geq 0 \). The initial conditions are, typically, \( \rho_0 = 0 \) and \( \beta_0 = 0 \). We will see that a solution to (1.2) exists and both \( \rho_t \) and \( X \beta_t \), \( t \geq 0 \), are unique. In addition, \( \rho_t \) is piece-wise linear, and there exists a solution path \( \beta_t \) that is piece-wise constant. The entire path can be computed at finitely many break points.

Linearized Bregman ISS has its solution path \( \{\rho_t, \beta_t\}_{t \geq 0} \) governed by the nonlinear differential inclusions:

\begin{align}
\dot{\rho}_t + \frac{1}{\kappa} \dot{\beta}_t &= \frac{1}{n} X^T (y - X \beta_t), \\
\rho_t &\in \partial \| \beta_t \|_1,
\end{align}

where \( \kappa > 0 \) is a constant. Compared to (1.2a), equation (1.3a) has the additional term \( \frac{1}{\kappa} \dot{\beta}_t \). As \( \kappa \to \infty \), (1.3) is reduced to (1.2), and the solution path of (1.3) may converge to that of (1.2) exponentially fast as \( \kappa \) increases. We will see that (1.3) has a unique solution path \( \rho_t \) and \( \beta_t \), \( t \geq 0 \), which are both continuous.

The discretizations of (1.2) and (1.3) are known as Bregman Iteration (equation (3.7) of [YODG08]) and Linearized Bregman Iteration (equations (5.19-20) of [YODG08]). They were introduced in the literature of variational imaging and compressive sensing before (1.2) and (1.3). Through a change of variable, Bregman Iteration becomes the iteration of the Augmented Lagrangian Method [Hes69, Pow67]. On the other hand, Linearized Bregman Iteration is a simple two-line iteration:

\begin{align}
\rho_{k+1} + \frac{1}{\kappa} \beta_{k+1} &= \rho_k + \frac{1}{\kappa} \beta_k + \frac{\alpha_k}{n} X^T (y - X \beta_k), \\
\beta_{k+1} &= \kappa \cdot \text{shrink}(z_{k+1}, 1),
\end{align}

which is evidently a forward Euler discretization to (1.3), where \( \alpha_k > 0 \) is a step size. Define \( z_k = \rho_k + \frac{1}{\kappa} \beta_k \). Then (1.4) can be simplified to:

\begin{align}
z_{k+1} &= z_k + \frac{\alpha_k}{n} X^T (y - X \beta_k) \\
\beta_{k+1} &= \kappa \cdot \text{shrink}(z_{k+1}, 1),
\end{align}
where the mapping shrink is defined component-wise as
\[
\text{shrink}(z, \lambda) := \text{sign}(z) \max\{|z| - \lambda, 0\}, \quad z, \lambda \in \mathbb{R}, \quad \lambda \geq 0.
\]
Note that \(\text{shrink}(z, \lambda)\) is the unique solution to the convex program:
\[
\min_{x \in \mathbb{R}} |x| + \frac{1}{2\lambda} (x - z)^2.
\]

1.1. Motivations and contributions. Our exposition is motivated by the fact that solution path \(\{\beta_t\}_{t \geq 0}\) of the differential inclusion (1.2) and the sequence \(\{\beta_k\}_{k \geq 0}\) of (1.4) are better than the points on the LASSO regularization path. In particular, while LASSO regularization path is always biased, \(\beta_t\) can be unbiased when the correct set of variables is reached.

To see this, consider the LASSO problem [Tib96],
\[
\min_{\beta} \lambda \|\beta\|_1 + \frac{1}{2n} \|y - X\beta\|_2^2,
\]
where for the convenience of comparison we replace the regularization parameter \(\lambda\) by \(t = 1/\lambda\) in the following equivalent form
\[
\min_{\beta} \|\beta\|_1 + \frac{t}{2n} \|y - X\beta\|_2^2.
\]
Aside from the obvious relation \(t = 1/\lambda\), solution \(\beta\) is piece-wise linear in \(\lambda\) [EHJT04] though not so in \(t\). Despite this, \(t\) will be convenient to our analysis by reflecting a nature of time evolution of the solution.

Since (1.7) is a convex program, \(\hat{\beta}_t\) is a solution to (1.7) if and only if it obeys the first-order optimality conditions
\[
(1.8a) \quad \frac{\hat{\beta}_t}{t} = \frac{1}{n} X^T (y - X\hat{\beta}_t),
\]
\[
(1.8b) \quad \hat{\beta}_t \in \partial \|\hat{\beta}_t\|_1,
\]
which are obtained by taking the subdifferential of the objective in (1.7).

It is well-known that LASSO solution \(\hat{\beta}_t\) is biased [FL01]. For example, considering the simple case that \(n = p = 1\), \(X\) is the identity and \(y \geq 0\), then (1.8) yields
\[
\hat{\beta}_t = \begin{cases} 0, & \text{if } t < 1/y; \\ y - 1/t, & \text{otherwise}, \end{cases}
\]
while (1.2) has the solution
\[
\beta_t = \begin{cases} 0, & \text{if } t < 1/y; \\ y, & \text{otherwise}, \end{cases}
\]
which is unbiased for \( t \geq 1/y \) as \( E[\beta_t] = E[y] = \beta^* \).

Moreover, the Linearized Bregman ISS (1.3) has the solution,

\[
\beta_t = \begin{cases} 
0, & \text{if } t < 1/y; \\
y(1 - e^{-\kappa(t - 1/y)}), & \text{otherwise},
\end{cases}
\]

which converges to the unbiased Bregman ISS estimator exponentially fast.

Let us discuss this phenomenon in the general setting. First, let the oracle estimator be the subset least-squares solution \( \tilde{\beta}^* \) given the true set of variables \( S \) by an oracle, whose nonzero entries are given by

\[
(1.12) \quad \tilde{\beta}^*_S = \left( \frac{1}{n} X_S^T X_S \right)^{-1} \frac{1}{n} X_S^T y = \beta^*_S + \left( \frac{1}{n} X_S^T X_S \right)^{-1} \frac{1}{n} X_S^T \epsilon.
\]

Clearly \( \tilde{\beta}^*_S \sim \mathcal{N}(\beta^*_S, \Sigma_n) \) where \( \Sigma_n = \frac{\sigma^2}{n} \left( \frac{1}{n} X_S^T X_S \right)^{-1} \). Since in expectation with respect to noise, \( E[\tilde{\beta}^*_S] = \beta^* \), \( \tilde{\beta}^*_S \) is an unbiased estimate of \( \beta^* \).

In reality we are not given the support set \( S \), so the following two properties are used to evaluate the performance of an estimator \( \hat{\beta} \).

1. **Model selection consistency**: \( \text{supp}(\hat{\beta}) = S \);
2. **Asymptotic normality**: \( \sqrt{n}(\hat{\beta} - \beta^*) \to \mathcal{N}(0, \Sigma^*) \), where

\[
\Sigma^* = \lim_{n \to \infty} n\Sigma_n = \sigma^2 \left( \lim_{n \to \infty} \frac{1}{n} X_S^T X_S \right)^{-1}.
\]

Since these properties hold for the oracle estimator, they are often referred to as the **oracle properties**.

A solution mapping \( \hat{\beta}_t : [0, \infty) \to \mathbb{R}^p \) gives a **regularization path**. Model selection consistency, also known as path consistency, refers to the existence of a point \( \hat{\beta}_\tau \) on this path that selects the correct variables, namely, \( \text{supp}(\hat{\beta}_\tau) = S \). Path consistency has been obtained for LASSO by establishing the stronger property of **sign consistency**, that is, \( \text{sign}(\hat{\beta}_\tau) = \text{sign}(\beta^*) \), under certain conditions such as those in \([ZY06, Zou06, YL07, Wai09]\). Provided that path consistency is reached at \( \tau \), the LASSO estimate \( \hat{\beta}_\tau \) is nonetheless biased since

\[
(1.13) \quad \hat{\beta}_{\tau,S} = \left( \frac{1}{n} X_S^T X_S \right)^{-1} \frac{1}{n} X_S^T y - \left( \frac{1}{n} X_S^T X_S \right)^{-1} \frac{1}{n} X_S^T \rho_\tau,
\]

where \( \rho_\tau = \text{sign}(\hat{\beta}_{\tau}) \in \partial \| \hat{\beta}_{\tau} \|_1 \). The first-term on the right-hand side equals the oracle estimator \( \hat{\beta}^*_S \), which is unbiased, whereas the second-term never vanishes and is the bias. Hence, the oracle properties are never completely met by LASSO.
The bias can be removed by a simple differentiation of LASSO solution. To see this, by multiplying \( t \) on both sides of (1.8a) and differentiating it with respect to \( t \), any point on the LASSO path satisfies

\[
\hat{\rho}_t = \frac{1}{n} X^T(y - X(\hat{\beta}_t + t\hat{\beta}_t)).
\]

With path consistency assumed at time \( t = \tau \), we have \( \beta_{\tau,i} = 0 \), \( \forall \ i \not\in S \), and from (1.14) we have

\[
\hat{\rho}_{\tau,S} = \frac{1}{n} X^T_S(y - X_S(\hat{\beta}_{\tau,S} + \tau\hat{\beta}_{\tau,S})).
\]

Generically, sign consistency occurs in a neighborhood and thus \( \hat{\rho}_{\tau,S} = 0 \). Therefore,

\[
\hat{\beta}_{\tau,S} + \tau\hat{\beta}_{\tau,S} = \left(\frac{1}{n} X^T_S X_S\right)^{-1} \frac{1}{n} X^T_S y = \beta^*_S,
\]

which is the oracle estimator without bias! This motivates us to replace \((\hat{\beta}_t + t\hat{\beta}_t)\) in (1.14) by just \( \hat{\beta}_t \), which gives the differential inclusions (1.2a) of Bregman ISS. Later we will show that the resulting \( \beta_t \) in (1.2) is indeed unbiased.

Therefore, in addition to giving the basic solution properties such as existence, uniqueness, and (dis)continuity, we also attempt to explain the good behaviors of the new solution paths and sequence by establishing their path consistency property. Basically we argue that

1. Under nearly the same conditions for LASSO [ZY06, Zou06, YL07, Wai09] that the covariates \( x_i \) are sufficiently uncorrelated and the signal \( \beta^*_S \) is strong enough, Bregman ISS (1.2) with a proper early stopping rule will return the oracle estimator;

2. Sign consistency and \( l_2 \)-error bounds of minimax rates can be generalized to the Linearized Bregman iteration (1.4) and its limit dynamics (1.3), under similar conditions.

Some computational aspects are reviewed in the next subsection.

1.2. Related work.

1.2.1. Regularization and other algorithms. For general penalized least square problems, [FL01] has shown that no convex penalty functions can fully achieve the oracle properties and thus one has to resort to non-convex regularization, whose global minimizer is, however, algorithmically difficult to locate. Alternatively, one can apply LASSO for variable selection and then
remove the bias in LASSO by solving a subset least squares in the second stage. On the other hand, [OBG+05] noticed that Bregman iteration may reduce bias, also known as contrast loss, in the context of Total Variation image denoising. In this paper, we shall see that dynamics (1.2) can automatically remove bias without any non-convexity or second-stage subset least squares. It is a different kind of regularization via early stopping.

Early stopping regularization has been studied widely in linear inverse problems, e.g. [EHN96], and recently in Boosting, e.g. [Fri01, BY02, YRC07]. In fact, Linearized Bregman iterations can be viewed as an extension of Landweber iteration (also called $L_2$-Boost in statistics),

$$\beta_{k+1} = \beta_k + \alpha_n X^T (y - X \beta_k),$$

which follows the primal path $\beta_t$ as a gradient descent method solving least square problem. To have solution sparsity, Linearized Bregman iterations (1.4) adds the dual path $\rho_t$ in favor of sparse solutions.

Linearized Bregman iteration (1.5) is shown in [Yin10] equivalent to the gradient ascent iteration applied to the Lagrange dual of the problem

$$\min_{\beta} \| \beta \|_1 + \frac{1}{2\kappa} \| \beta \|_2^2 \quad \text{subject to} \quad X \beta = y. \quad (1.16)$$

In particular, $\beta_k$ converges to the unique solution of (1.16) at a linear rate (as long as $X \neq 0$ and $X \beta = y$ has a solution); see [LY13]. In addition, for sufficiently large $\kappa$, the solution to (1.16) is a solution to the basis pursuit model [CDS98], which is (1.16) without $\frac{1}{2\kappa} \| \beta \|_2^2$. In noisy settings, early stopping regularization is necessary for signal recovery. The results in this paper basically say that under nearly the same condition as LASSO, Bregman ISS with early stopping regularization may recover the signal without bias. We note that such dynamics can be easily extended to general settings with differentiable convex loss and non-differentiable convex penalty, e.g. Linearized Bregman iteration in matrix completion [CCS10].

One should not confuse Linearized Bregman iteration (1.5) with iterative soft-thresholding algorithm (ISTA), which has been widely used under different names in the literature (for example, see [DJ95, Don95, CDLL98, DD02, DDD04]),

$$\beta_{k+1} = \text{shrink}(\beta_k + \frac{\alpha_k}{n} X^T (y - X \beta_k), \lambda_k).$$

By moving the shrinkage operator to a different place in (1.5), Linearized Bregman iteration generates a sparse solution path with early stopping regularization, while ISTA exploits $\lambda_k$ as the regularization parameter and its iterates converge to a LASSO solution.
1.2.2. Parallel and distributed computing. It is very easy to implement iteration (1.5) in parallel and distributed manners and apply it to very large-scale datasets. Suppose
\[ X = [X_1, X_2, \ldots, X_L] \in \mathbb{R}^{n \times p}, \]
where \( X_\ell \)'s are submatrices stored in a distributed manner (on a set of networked workstations). The sizes of \( X_\ell \)'s are flexible and can be chosen for good load balancing. Let each workstation \( \ell \) hold data \( y \) and \( X_\ell \), and variables \( z_{k,\ell} \) and \( w_{k,\ell} := X_\ell \beta_{k,\ell} \), which are parts of \( z_k \) and summands of \( w_k := X \beta_k \), respectively. The iteration (1.5) is carried out as
\[
\begin{align*}
  &\text{for } \ell = 1, \ldots, L \text{ in parallel: } \\
  &\quad z_{k+1,\ell} = z_{k,\ell} + \frac{\alpha_k}{n} X_\ell^T (y - w_k), \\
  &\quad w_{k+1,\ell} = \frac{1}{\kappa} X_\ell \text{shrink}(z_{k+1,\ell}, 1), \\
  &\text{all-reduce summation: } w_{k+1} = \sum_{\ell=1}^L w_{k+1,\ell},
\end{align*}
\]
where the all-reduce step collects inputs from and then returns the sum to all the \( L \) workstations. It is the sum of \( L \) \( n \)-dimensional vectors, so no matter how the all-reduce step is implemented, the communication cost is independent of \( p \). It is important to note that the algorithm is not changed at all. In particular, distributing the data into more computing units, i.e., increasing \( L \), does not increase the number of iterations. Therefore, the parallel implementation is nearly embarrassingly parallel and truly scalable. In addition, it is also possible to develop implementations for data divided into blocks of rows of \( X \) or even smaller subblocks that split both rows and columns. Recently, (1.5) has also been extended in [YLYR13] to a decentralized setting where not only data and computation are distributed but communication is restricted to computing units with direct communication links, so there is no data fusion center or long distance communication. The scheme fits sensor network or multi-party regression over the internet, where long-distance communication incurs long delays and high costs.

1.3. Notation and assumptions. We introduce the following notation and assumptions to \( \beta^*, X \), and \( \epsilon \).

- Let the true support be denoted by \( S = \text{supp}(\beta^*) = \{i : \beta^*_i \neq 0\} \), and \( T = S^c \) be its complement. Clearly, \( S \cup T = \{1, \ldots, p\} \).
- \( X_S \) denotes the submatrix of \( X \) formed by the columns of \( X \) in \( S \), which are assumed to be linearly independent. Similarly define \( X_T \) so that \( [X_S \ X_T] = X \).
• Assume $\epsilon \sim \mathcal{N}(0, \sigma^2 I_n)$. It can generalize to sub-Gaussian without violating most of our results.

Define $\langle u, v \rangle = u^T v$ and $\langle u, v \rangle_n = \frac{1}{n} u^T v$ for $u, v \in \mathbb{R}^n$. Hence $\|u\|_n = \frac{1}{\sqrt{n}} \|u\|$.

Let $X^* = \frac{1}{n} X^T$ be the adjoint operator of $X$ with respect to inner product $\langle \cdot, \cdot \rangle_n$. Let the largest and the smallest nonzero magnitudes of $\beta^*$ be $\beta^*_\text{max} := \max(|\beta^*_i| : i \in S)$ and $\beta^*_\text{min} := \min(|\beta^*_i| : i \in S)$, respectively. Similarly define $\tilde{\beta}^*_\text{max}$ and $\tilde{\beta}^*_\text{min}$ for the oracle estimator $\tilde{\beta}^*$ in (1.12). The dependence of $\rho_t$ and $\beta_t$ (or equivalently $\rho(t)$ and $\beta(t)$) on $t$ is omitted where it is clear from the context. For the reason to be discussed in Section 2, we shall assume that $\rho_t$ is right continuously differentiable and $\beta_t$ is right continuous.

Throughout the paper, given two numbers $a$ and $b$, let $a \lor b := \max(a, b)$.

1.4. Outline. In the rest of this paper, we establish basic solution properties of Bregman and Linearized Bregman ISS in Section 2. Section 3 and Section 4 describe statistical consistency properties of Bregman ISS and their generalizations to Linearized Bregman ISS/discretization, respectively. Section 5 is dedicated to the ideas of proofs. Section 6 provides some preliminary numerical results. Discussions and conclusions are summarized in Section 7.

2. Bregman and Linearized Bregman solution paths. The solution to Bregman ISS (1.2) is a piece-wise regularization path given iteratively as follows, starting with $k = 0, t_0 = 0$, and $\rho_0 = \beta_0 = 0$:

1. set $t_{k+1} := \sup \{ t > t_k : \rho_{t_k} + \frac{t-t_k}{n} X^T (y - X \beta_{t_k}) \in \partial \|\beta_{t_k}\|_1 \}$ if $t_{k+1} = \infty$, then exit;
2. set $\rho_{t_{k+1}} := \rho_{t_k} + \frac{t_{k+1}-t_k}{n} X^T (y - X \beta_{t_k})$;
3. set $S_{k+1} := \{i : (\rho_{t_k})_i = 1\}$ and $T_{k+1} = \{1, \ldots, p\} \setminus S_{k+1}$;
4. set $\beta_{t_{k+1}}$ as any solution to

$$
\min_{\beta} \|y - X \beta\|_2^2 \quad \text{subject to} \quad (\rho_{t_{k+1}})_i \beta_i \geq 0 \quad \forall \ i \in S_{k+1}, \\
\beta_j = 0 \quad \forall \ j \in T_{k+1}.
$$ (2.1)

5. set $k = k + 1$ and go to Step 1.

Paper [BMBO13] gives an algorithm but does not establish the uniqueness of solution path. One can show that the solution to (1.2) is piece-wise:

$$
\begin{cases}
\rho_t = \rho_{t_k} + \frac{t-t_k}{t_{k+1}-t_k} \rho_{t_{k+1}}, \\
\beta_t = \beta_{t_k},
\end{cases} \quad t \in [t_k, t_{k+1}).
$$ (2.2)

In other words, $\rho_t$ is piece-wise linear and $\beta_t$ is piece-wise constant. The following theorem presents some general conditions to ensure the existence and uniqueness of solution path.
Theorem 2.1 (Solution existence and uniqueness for Bregman ISS). Let \( \rho_t \) be right continuously differentiable and \( \beta_t \) be right continuous. Then, a solution to (1.2) is given by \((\beta_t, \rho_t)\) generated by the above algorithm. Solution \( \rho_t \) and \( X\beta_t \) are unique. In addition, if the columns \( x_i \) of \( X \) for \( i \in \text{supp}(\beta_t) \) are linearly independent for \( t \geq 0 \), then \( \beta_t \) is also unique.

Proof. The existence part follows from [BMBO13]. We show that the uniqueness part. Define \( f(\beta) := \frac{1}{2n} \|y - X\beta\|^2 \). Then, the differential inclusion (1.2) is equivalent to

\[
(2.3a) \quad \dot{\rho}_t = -\nabla f(\beta_t),
(2.3b) \quad \rho_t \in \partial \|\beta_t\|_1,
\]

Let \( S^+_t := \{i : (\rho_t)_i = 1\}, S^-_t := \{i : (\rho_t)_i = -1\}, \) and \( S_t = S^+_t \cup S^-_t \). By (1.2b), in the case of \( S_t = \emptyset \), we have \( \beta_t = 0 \), so \(-\nabla f(\beta_t) = -\nabla f(0) \) is unique. In the case of \( S_t \neq \emptyset \), we show below that \( X\beta_t \) and \(-\nabla f(\beta_t) \) are both unique. The uniqueness of \( \rho_t \) follows from these results and (2.3a).

In fact, (1.2a) and (1.2b) impose the following constraints on \( \beta_t \):

\[
(2.4) \quad \begin{cases} 
(\beta_t)_i \geq 0 \text{ and } (\nabla f(\beta_t))_i \geq 0, & \forall i \in S^+_t, \\
(\beta_t)_i \leq 0 \text{ and } (\nabla f(\beta_t))_i \leq 0, & \forall i \in S^-_t, \\
(\beta_t)_i = 0, & \forall i \not\in S_t.
\end{cases}
\]

To see how \( \nabla f(\beta_t) \) is involved, notice that \((\nabla f(\beta_t))_i \geq 0 \) must hold for \( \forall i \in S^+_t \) since \((\rho_t)_i \in [-1,1] \) is already at its maximal value 1 and \( \nabla f(\beta_t) < 0 \) is forbidden as it would further increase \((\rho_t)_i \) to an impossible value. The same argument holds for \((\nabla f(\beta_t))_i \leq 0 \) for \( \forall i \in S^-_t \).

Furthermore, we will have \((\beta_t)_i \cdot (\nabla f(\beta_t))_i = 0 \) for all \( i \). To see this, assume \((\beta_t)_i \neq 0 \). Then by the right continuity assumption, there exists an interval \([t,t+\epsilon)\) in which \( \beta_t \) remains nonzero with the same sign. By (2.3b), \((\rho_t)_i \) will remain either +1 or -1 in the same interval, so \((\nabla f(\beta_t))_i = 0 \). On the other hand, assume \((\nabla f(\beta_t))_i \neq 0 \). Then by (2.3a), \( \rho_t \) will change and thus it cannot stay either +1 or -1. By the right continuity of \( \beta_t \), it must hold that \((\beta_t)_i = 0 \). Therefore, we have the addition constraints

\[
(2.5) \quad (\beta_t)_i \cdot (\nabla f(\beta_t))_i = 0.
\]
Conditions (2.4) and (2.5) are precisely the KKT optimality conditions for

\[
\min_{\beta} \ f(\beta)
\]

subject to \( \beta_i \geq 0, \ \forall i \in S_t^+ \),

\( \beta_i \leq 0, \ \forall i \in S_t^- \),

\( \beta_i = 0, \ \forall i \notin S_t \),

which is identical to (2.1) except (2.1) specifies the time \( t_{k+1} \). Let \( \beta_t \) be the solution to problem (2.6).

In general, if \( f \) is strictly convex, then the solution \( \beta_t \) is unique. In our case, \( f \) is not necessarily strictly convex, but \( f = g(X\beta) \) for a strictly convex function \( g \). Therefore, \( X\beta_t \) is unique, and thus so is \( \nabla f(\beta_t) = X^T \nabla g(X\beta_t) \). Lastly, \( \beta_t \) is unique if the columns of \( X \) corresponding to nonzero entries of \( \beta_t \) are linearly independent since \( X\beta_t \) is unique.

The existence and uniqueness of Linearized Bregman ISS is much simpler as shown in the following theorem.

**Theorem 2.2 (Solution existence and uniqueness for Linearized Bregman ISS).** Let \( \rho_t \) be right continuously differentiable and \( \beta_t \) be right continuous. Then (1.3) has a unique solution.

**Proof.** Let \( z_t = f(\rho_t, \beta_t) = \rho_t + \frac{1}{\kappa} \beta_t \), then \( f \) is an injective function from the admissible set \((\rho, \beta)\) to \( C^1 \) in variable \( t \) and \( \beta_t = \kappa \text{shrink}(z_t, 1) \). Now differential inclusion (1.3) becomes the ODE

\[
\dot{z}_t = \frac{1}{\kappa} X^T (y - \kappa X \cdot \text{shrink}(z_t, 1)) =: g(z_t)
\]

Obviously, \( g(x) \) is Lipschitz continuous. Therefore, the Picard-Lindelöf Theorem implies that there exists a unique solution to this ODE, which leads to the solution of (1.3).

We note that the solution of (1.3), though not piece-wise linear or constant, can still be computed in a piece-wise closed form where on each piece, the signs of \( \beta_t \) remain unchanged. This is left to the reader.

Provided that sign consistency is met by a point on the path at \( t = \tau \), (2.1) returns an oracle solution as it is a least-squares problem subject to only sign constraints. Hence, natural questions are: what conditions will guarantee sign consistency? And, how to determine \( \tau \)? In the sequel, we are going to provide an answer to this question. Throughout the remaining of this paper, we assume that \( \rho_t \) is right continuously differentiable and \( \beta_t \) is right continuous, so the existence and uniqueness of solution paths are guaranteed.
3. Consistency of Bregman ISS Dynamics. In this section necessary and sufficient conditions are established for noisy sparse signal recovery with Bregman ISS (1.2).

3.1. Assumptions.

(A1) **Restricted Strong Convexity**: there is a $\gamma \in (0, 1]$,

$$X_S^* X_S \geq \gamma I.$$  

(A2) **Irrepresentable Condition**: there is a $\eta \in (0, 1)$,

$$\left\| X_S^* X_S^\dagger \right\|_\infty = \left\| \frac{1}{n} X_T X_S \left( \frac{1}{n} X_S^T X_S \right)^{-1} \right\|_\infty \leq 1 - \eta$$

where $X_S^\dagger := X_S \left( \frac{1}{n} X_S^T X_S \right)^{-1}$.

Condition A1 says that the Hessian matrix of the empirical risk $\frac{1}{2n} \| y - X\beta \|_2^2$ restricted on the index set $S \times S$ is strictly positive definitive, so the empirical risk is strongly convex when restricted on the support set $S$. Such a condition is necessary in the sense that once it fails, $X_S$ will be linearly dependent and no unique representation is possible under the basis $X_S$.

Condition A2 says that the absolute row sums of matrix $X_S^* X_S^\dagger$ are all less than one. It has been proposed independently under a variety of names, e.g. Exact Recovery Condition [Tro04], Irrepresentable Condition [ZY06], among [YL07, Zou06]. Here we adopt the name in [ZY06] as it refers to the fact that the regression coefficients of $X_S$ for response $X_j$ ($j \in T$) all have $\ell_1$-norm less than one, i.e.

$$\beta_j' = \arg \min_{\beta \in \mathbb{R}^s} \frac{1}{2n} \| X_j - X_S \beta \|_2^2 \implies \| \beta_j' \|_1 < 1,$$

so in this sense one cannot represent the irrelevant covariates $X_T$ by the relevant ones $X_S$ effectively.

Neither A1 nor A2 can be checked when the support set $S$ of signal is not known. Alternatively we can use a more strict but checkable condition proposed in [DH01].

(A3) **Mutual Incoherence Condition**:

$$\mu := \max_{i,j} \left| \frac{1}{n} \langle X_i, X_j \rangle \right| < \frac{1}{(2s - 1)}, \quad s = |S|.$$
It can be shown [Tro04, CW11] that once A3 holds, then A1 and A2 simultaneously hold with
\[
\gamma = 1 - \mu(s - 1)
\]
since \((1 - \mu(s - 1))I_S \leq X_S^*X_S \leq (1 + \mu(s - 1))I_S\), and
\[
\eta = \frac{1 - \mu(2s - 1)}{1 - \mu(s - 1)}.
\]
We note that condition A3 is shown to be sharp in the noisy case in [CWX10]. With these one can translate all the theoretical results with condition A1 and A2 into condition A3.

3.2. Mean Bregman ISS Path versus LASSO Path. As we have seen in Section 1.1 near equation (1.14), Bregman ISS (1.2) can be derived by differentiating LASSO’s KKT conditions. Such a relation can be seen precisely by considering the consistency conditions of LASSO on the following temporal mean path of Bregman ISS:

\[
\bar{\beta}(t) := \frac{1}{t} \int_0^t \beta(s) ds.
\]

According to Theorem 2.1 and Condition A1, Bregman ISS path \(\beta_t\) is unique and thus \(\bar{\beta}(t)\) is well defined as long as \(\text{supp}(\beta(s)) \subseteq S\), \(s \in [0, t]\), where \(S\) is the true support.

A connection between Bregman ISS and LASSO lies in the same condition under which their paths from start to time \(t\) are supported within the true support \(S\). In addition, the Bregman ISS mean path \(\bar{\beta}(t)\) is identical to the LASSO path if the Bregman ISS path is incremental with only adding variables, but without dropping. In general, the two paths are distinct.

**Theorem 3.1.** Let \((\beta_t, \rho_t)\) be either the Bregman ISS path (1.2) or the LASSO path (1.8) with \(\rho(t) \in \partial\|\beta_t\|_1\). Assume that for all \(t \leq \tau\),

\[
\|X_T^*X_S^*\rho_S(t) + tX_T^*P_T\epsilon\|_\infty < 1,
\]

where \(P_{S^\perp} = I - P_S = I - X_S^*X_S^*\) is the projection matrix onto \(\text{im}(X_S)^\perp\). Then for all \(t \leq \tau\),

A. the Bregman ISS path, its mean path, and the LASSO path all have supports in \(S\);

B. the mean Bregman ISS path \(\bar{\beta}(1/\lambda)\) is piecewise linear with \(\lambda = 1/t\);
C. if the Bregman ISS path is incremental in the sense that $S_t = \text{supp}(\beta_t)$ satisfies $S_t \subseteq S_{t'} \subseteq S$ for all $t \leq t' \leq \tau$, then the mean Bregman ISS path is identical to the LASSO path; but they are distinct in general.

Remark 3.1. In particular in noiseless setting, $\epsilon = 0$, (3.2) becomes

$$\|X^*_T X^T S \rho_S(t)\|_\infty < 1$$

or dropping $\rho_S(t)$ by

$$\|X^*_T X^T \|_\infty = \|X^*_T X S (X^*_S X_S)^{-1}\|_\infty < 1$$

which is sufficient and necessary to guarantee that both Bregman ISS, LASSO, and OMP [Tro04] recovers the sparse signal in noiseless setting; once it is violated there is some $S$-sparse signal for which these methods fail.

Proof of Theorem 3.1. Assume there exists a $\tau \geq 0$, such that for all $t \leq \tau$, solution path $\beta(t)$ satisfies $\text{supp}(\beta(t)) \subseteq S$. Then Bregman ISS (1.2) splits into

$$\dot{\rho}_S = -X^*_S X_S (\hat{\beta}_S - \beta^*_S) + X^*_S \epsilon,$$

$$\dot{\rho}_T = -X^*_T X_S (\hat{\beta}_S - \beta^*_S) + X^*_T \epsilon. \tag{3.3a, 3.3b}$$

From (3.3a) one gets the Bregman ISS solution

$$\beta_S(t) = \beta^*_S - (X^*_S X_S)^{-1} \rho_S + (X^*_S X_S)^{-1} X^*_S \epsilon,$$

which leads to the following equation by plugging into (3.3b)

$$\dot{\rho}_T = X^*_T X^T S \dot{\rho}_S + X^*_T P \epsilon. \tag{3.4}$$

Integration on both sides of this equation and setting

$$\|\rho_T(t)\|_\infty = \|X^*_T X^T S \rho_S(t) + tX^*_T P \epsilon\|_\infty < 1 \tag{3.5}$$

which ensures that $\beta_T(t) = 0$. So is the mean path.

On the other hand, LASSO starts from the KKT condition (1.8) which splits into

$$\dot{\rho}_S / t = -X^*_S X_S (\hat{\beta}_S - \beta^*_S) + X^*_S \epsilon \tag{3.7a}$$

$$\dot{\rho}_T / t = -X^*_T X_S (\hat{\beta}_S - \beta^*_S) + X^*_T \epsilon \tag{3.7b}$$

Following the same trick above one can see the same condition (3.6) is met for LASSO to ensure $\hat{\beta}_T(t) = 0$. This finishes the proof of part A.
As to part B, for \( t \leq \tau \), the mean path is obtained by integration on (3.3a)

\[
(3.8) \quad \bar{\beta}_S(t) = \frac{1}{t} \int_0^t \beta_S(s) ds = \beta_S^* - \frac{1}{t} (X_S^* X_S)^{-1} \rho_S(t) + (X_S^* X_S)^{-1} X_S^* \epsilon.
\]

Equation (2.2) implies that \( \frac{1}{t} \rho_t = \frac{1}{t} \rho_{t_k} + \frac{1-t_k/t}{t_{k+1}-t_k} \rho_{t_{k+1}} \), which is piecewise linear with respect to \( \lambda = 1/t \).

To see part C, let \( S_t = \text{supp}(\beta_t) \) for Bregman ISS. If for all \( s \leq t \leq \tau \), \( S_s \subseteq S_t \subseteq S \), then similar reasoning as above implies that the Bregman ISS path satisfies

\[
(3.9) \quad \bar{\beta}_{S_t}(t) = \beta_{S_t}^* - \frac{1}{t} (X_{S_t}^* X_{S_t})^{-1} \rho_{S_t}(t) + (X_{S_t}^* X_{S_t})^{-1} X_{S_t}^* \epsilon.
\]

For such incremental processes, \( \rho_{S_t}(t) = \text{sign}(\beta_{S_t}(t)) = \text{sign}(\bar{\beta}_{S_t}(t)) \) which meets the LASSO path equation

\[
(3.10) \quad \hat{\beta}_{S_t}(t) = \beta_{S_t}^* - \frac{1}{t} (X_{S_t}^* X_{S_t})^{-1} \hat{\rho}_{S_t}(t) + (X_{S_t}^* X_{S_t})^{-1} X_{S_t}^* \epsilon,
\]

where \( \hat{S}_t = \text{supp}(\hat{\beta}_t) \) for LASSO. But such a relation is lost when variable dropping happens.

Despite of the difference to the LASSO path, the mean Bregman ISS path may reach statistical model-selection consistency under the same conditions as LASSO.

**Theorem 3.2 (Sign Consistency of Mean Path).** Let

\[
\bar{\tau} := \frac{\eta}{2 \sigma} \sqrt{n \log p} \left( \max_{j \in T} \| X_j \|_n \right)^{-1}.
\]

Assume that both (A.1) and (A.2) hold. Then the following holds.

A. **(No-false-positive)** the mean path has no-false-positive before time \( \bar{\tau} \), i.e., \( \forall t \leq \bar{\tau} \) \( \text{supp}(\bar{\beta}_t) \subseteq S \), with probability at least \( 1 - \frac{2}{p \sqrt{\bar{\tau} \log p}} \);

B. **(No-false-negative for Mean Path)** moreover if the signal is strong enough such that \( \beta_{\min}^* > c_1/\bar{\tau} \),

\[
c_1 = \left( \frac{\eta}{\sqrt{\gamma}} \max_{j \in T} \| X_j \|_n + \| (X_S^* X_S)^{-1} \|_\infty \right),
\]

then with probability at least \( 1 - \frac{2}{p \sqrt{\bar{\tau} \log p}} \), the mean path \( \bar{\beta}_\bar{\tau} \) has no false-negative, i.e. \( \text{sign}(\bar{\beta}_\bar{\tau}) = \text{sign}(\beta^*) \).
3.2. Remarks. Under the same conditions as LASSO with $\lambda^* = 1/\bar{\tau}$ [Wai09], the mean path $\bar{\beta}$ of Bregman ISS reaches sign-consistency. These conditions are sufficient and necessary in the sense that once violated, there exists an instance such that the probability of failure will be larger than $1/2$ due to noise. In this sense, the mean path estimator $\bar{\beta}(\bar{\tau})$ is “statistically equivalent” to the LASSO estimator.

The mean Bregman ISS path geometrically sheds light on why LASSO incurs bias while Bregman ISS can avoid it. The LASSO path, like the mean Bregman ISS path, involves some kind of averaging that ensures the path continuity but causes bias. The Bregman ISS path is piecewise constant, allows it to be bias-free.

Now we need to answer the following question: what are conditions to ensure the sign consistency of the Bregman ISS path?

3.3. Consistency of Bregman ISS. The following theorem tells us that under the irrepresentable (incoherence) condition, the Bregman ISS dynamics always evolves in the support of true signals in the early stage; furthermore if the signal is strong enough then the dynamics will pick up all the true variables before selecting any incorrect ones. When such a sign consistency is reached, Bregman ISS returns the oracle estimator which is unbiased.

Theorem 3.3 (Sign Consistency of Bregman ISS). Let

$$\bar{\tau} := \frac{\eta}{2\sigma} \sqrt{\frac{n}{\log p}} \left( \max_{j \in T} \|X_j\|_n \right)^{-1}.$$

Assume that both (A.1) and (A.2) hold. Then Bregman ISS (1.2) has paths satisfying:

A. (No-false-positive) the path has no-false-positive before time $\bar{\tau}$, i.e. $\forall t \leq \bar{\tau} \supp(\beta_t) \subseteq S$, with probability at least $1 - \frac{2}{p \sqrt{s \log p}}$;

B. (Sign-consistency) moreover if the signal is strong enough such that

$$(3.11) \quad \beta_{\min}^* \geq \left( \frac{4\sigma}{\gamma^{1/2}} \sqrt{\frac{8\sigma(2 + \log s)}{\gamma \eta}} \max_{j \in T} \|X_j\|_n \right) \sqrt{\frac{\log p}{n}}$$

Then with probability at least $1 - \frac{2}{p \sqrt{s \log p}}$, $\text{sign}(\beta_t) = \text{sign}(\beta^*)$.

Remark 3.3. Once the sign consistency holds, $\beta(t)$ meets the oracle estimator $\beta^*$ which is unbiased and has a $l_2$-error rate $\| \beta(t) - \beta^* \|_2 \leq O(\sigma \sqrt{s \log s / n})$, even better than the $l_2$-error rate $O(\sigma \sqrt{s \log p / n})$ for the LASSO estimator which is minimax optimal up to a logarithmic factor [RWY11].
To have sign consistency, Theorem 3.3 makes a strong signal condition with a lower bound on $\beta^*_\min$. However even without such a strong signal assumption, the minimax optimal $l_2$-error rates can be achieved disregarding sign consistency.

**Theorem 3.4 (Minimax Optimal $l_2$-Error Bound).** Assume that both (A1) and (A2) hold. There is a $\tau \in [0, \bar{\tau}]$ such that with probability at least $1 - \frac{2}{p^{\sqrt{n} \log p}}$,

$$\|\beta_t - \beta^*\|_2 \leq \frac{2\sigma}{\eta \gamma} \left( 4 \max_{j \in T} \|X_j\|_n + \eta \sqrt{\gamma} \right) \sqrt{\frac{s \log p}{n}}.$$

The existence of such $\tau$ does not ensure us to find it easily. However one can use $\bar{\tau}$ at a cost of enlarging the constants by a square root of condition number of $\Sigma_S = X^*_S X_S$.

**Corollary 3.1.** Under the same condition of Theorem 3.4 and assuming an upper eigenvalue bound $X^*_S X_S \leq \gamma_{\max} I_S$, then the following holds for all $t \in [\tau, \bar{\tau}]$ with probability at least $1 - \frac{2}{p^{\sqrt{n} \log p}}$

$$\|\beta_t - \beta^*\|_2 \leq \frac{2\sigma \sqrt{K(X^*_S X_S)}}{\eta \gamma} \left( 4 \max_{j \in T} \|X_j\|_n + \eta \sqrt{\gamma} \right) \sqrt{\frac{s \log p}{n}}$$

where $K(X^*_S X_S) = \gamma_{\max} / \gamma$ is the condition number of $X^*_S X_S$.

All the results in this subsection follow from the more general results on Linearized Bregman ISS (1.3) in the next section by taking $\kappa \to 0$. Therefore we omit the proofs.

4. Generalizations to Linearized Bregman ISS and Its Discretization. In this section, we state a general consistency result for Linearized Bregman ISS (1.3) and Linearized Bregman Iterations (1.4) whose proof will be given in the next section.

4.1. Consistency of Linearized Bregman ISS. The following theorem establishes general conditions for statistical consistency of Linearized Bregman ISS (LBISS) (1.3).

**Theorem 4.1 (Consistency of LBISS).** Let

$$\bar{\tau} := \frac{(1 - B/(\kappa \eta)) \eta}{2\sigma} \sqrt{\frac{n}{\log p \left( \max_{j \in T} \|X_j\|_n \right)^{-1}}}.$$
Assume $\kappa$ is big enough to satisfy

$$
\beta_{\text{max}}^* + 2\sigma \sqrt{\frac{\log p}{\gamma n}} + \frac{\|X^*\beta\|_2 + 2\sigma \sqrt{\pi \log n}}{n \sqrt{\gamma}} \triangleq B \leq \kappa \eta.
$$

Then (1.3) has paths satisfying

**A. (No-false-positive)** the path has no-false-positive before time $\tau$, i.e.,

$$
\forall t \leq \tau \text{ supp}(\beta_t) \subseteq S,
$$

with probability at least $1 - \frac{2}{n \sqrt{\pi \log n}} - \frac{1}{n \sqrt{\pi \log n}}$.

**B. (No-false-negative for Mean Path)** moreover if the signal is strong enough such that $eta_{\text{min}}^* > c_1/\tau$,

$$
c_1 = \left( \frac{(1 - B/(\kappa \eta)) \eta}{\sqrt{\gamma} \max_{j \in T} \|X_j\|_n} + (1 + B/\kappa \eta) \|X^*_S X_S^{-1}\|_{\infty} \right),
$$

then with probability at least $1 - \frac{2}{n \sqrt{\pi \log n}} - \frac{1}{n \sqrt{\pi \log n}}$, the mean path $\bar{\beta}(t)$ satisfies $\text{sign}(\bar{\beta}_t) = \text{sign}(\beta^*)$.

**C. (Sign-consistency for LBISS)** Moreover if the smallest magnitude $\beta_{\text{min}}^*$ is strong enough and $\kappa$ big enough such that

$$
\beta_{\text{min}}^* \geq \frac{4\sigma}{\gamma^{1/2}} \sqrt{\frac{\log p}{n}},
$$

$$
\frac{8 + 4 \log s}{\beta_{\text{min}}^*} + \frac{1}{\kappa} \log \left( \frac{3 \|\beta^*\|_2}{\beta_{\text{min}}^*} \right) \leq \tau,
$$

then with probability at least $1 - \frac{2}{n \sqrt{\pi \log p}} - \frac{1}{n \sqrt{\pi \log n}}$, $\text{sign}(\bar{\beta}_t) = \text{sign}(\beta^*)$.

**D. ($l_2$-bound)** For some constant $C$ and $\kappa$ large enough to satisfy

$$
\frac{4}{C \gamma} \sqrt{\frac{n \log p}{\log p}} + \frac{1}{2 \kappa \gamma} (1 + \log \frac{n \|\beta^*\|_2^2 + 4\sigma^2 s \log p/\gamma}{C^2 s \log p}) \leq \tau,
$$

there is a $\tau \in [0, \tau]$ such that $\|\beta_t - \beta^*\|_2 \leq (C + \frac{2\sigma}{\gamma^{1/2}}) \sqrt{\frac{s \log p}{n}}$ with probability at least $1 - \frac{2}{n \sqrt{\pi \log p}} - \frac{1}{n \sqrt{\pi \log n}}$.

**Remark 4.1.** **A.** For sign-consistency of LBISS,

$$
\beta_{\text{min}}^* \geq \left( \frac{4\sigma}{\gamma^{1/2}} \sqrt{\frac{8\sigma (2 + \log s) \max_{j \in T} \|X_j\|_2}{\gamma \eta}} \right) \sqrt{\frac{\log p}{n}}
$$

is enough to guarantee the existence of $\kappa$. 
B. For $l_2$-consistency

$$C \geq \frac{8 \sigma \left( \max_{j \in T} \|X_j\|_n \right)}{\eta \gamma}$$

is enough to guarantee the existence of $\kappa$.

C. Taking $\kappa = \infty$, we get the Theorem 3.3 for Bregman ISS.

D. An $l_2$-error bound of the same rate for estimator $\beta(\bar{\tau})$ can be established using the monotonicity of $\|X_S(\bar{\beta}^*_S - \beta_S(t))\|_2$ (see Appendix) for $t \leq \bar{\tau}$,

$$\|\beta(\bar{\tau}) - \bar{\beta}\|_2 \leq \frac{\|X_S(\beta_S(\bar{\tau}) - \bar{\beta}^*_S)\|_2}{\sqrt{n \gamma}} \leq \frac{\|X_S(\beta_S(\tau) - \bar{\beta}^*_S)\|_2}{\sqrt{n \gamma}}, \quad \tau \leq \bar{\tau}$$

where $K(X_S^*X_S)$ is the condition number of $X_S^*X_S$.

4.2. Consistency of Linearized Bregman iterations. The following theorem establishes statistical consistency conditions for Linearized Bregman Iteration (1.4).

**Theorem 4.2 (Consistency of Linearized Bregman Iterations).** Let $t_n = \sum_{k=0}^{n-1} \alpha_k$ and

$$\bar{\tau} := \left(1 - \frac{B / (\kappa \eta)}{2 \sigma}\right) \eta \sqrt{\frac{n}{\log p}} \left( \max_{j \in T} \|X_j\|_n \right)^{-1}.$$  

Assume that $\kappa$ is big enough to satisfy

$$\beta^*_{\text{max}} + 2\sigma \sqrt{\frac{\log p}{\gamma n}} + \frac{\|X\beta^*\|_2 + 2\sqrt{s \log n}}{n \sqrt{\gamma}} \leq B \leq \kappa \eta,$$

and step size $\alpha$ is small such that $\kappa \alpha \|X_S^*X_S\| < 2$. Then any solution path of (1.3) satisfies

A. **(No-false-positive)** for all $n$ s.t. $t_n \leq \bar{\tau}$, the path has no-false-positive with probability at least $1 - \frac{2}{\nu \pi \log p} - \frac{1}{n \sqrt{\pi \log n}}$, $\text{supp}(\beta_k) \subseteq S$;

B. **(Sign-consistency)** moreover if the smallest magnitude $\beta^*_{\text{min}}$ is strong enough and $\kappa$ is big enough to ensure

$$\beta^*_{\text{min}} \geq \frac{4 \sigma}{\gamma^{1/2}} \sqrt{\frac{\log p}{n}}.$$
\[
\frac{8 + 4 \log s}{\bar{\gamma} \beta_{\min}} + \frac{1}{\kappa \bar{\gamma}} \log \left( \frac{3 \beta^*}{\beta_{\min}} \right) + 3\alpha \leq \bar{\tau},
\]
where \(\bar{\gamma} = \gamma (1 - \kappa \alpha \|X_S X_S^*\|/2)\), then with probability at least \(1 - \frac{2}{p\sqrt{\pi \log p}} - \frac{1}{n \sqrt{\pi \log n}}\), \(\text{sign}(\beta_{k^*}) = \text{sign}(\beta^*)\) for \(k^* = \max\{k : t_k \leq \bar{\tau}\}\).

C. \((l_2\text{-bound})\) for some large enough constants \(\kappa\) and \(C\) such that
\[
\frac{4}{C \bar{\gamma}} \sqrt{\frac{n}{\log p}} + \frac{1}{2\kappa \bar{\gamma}} \left( 1 + \log \frac{n \beta^*}{2} + 4\sigma^2 s \log p/\gamma \right) + 2\alpha \leq \bar{\tau},
\]
with probability at least \(1 - \frac{2}{p\sqrt{\pi \log p}} - \frac{1}{n \sqrt{\pi \log n}}\), there is a \(k^*\), \(t_{k^*} \leq \bar{\tau}\), such that \(\|\beta_{k^*} - \beta^*\|_2 \leq (C + \frac{2\sigma}{\gamma^{1/2}}) \sqrt{\frac{s \log p}{n}}\).

Remark 4.2.  
A. Taking \(\alpha \to 0\), we have \(\bar{\gamma} = \gamma\), and Theorem 4.1 for Linearized Bregman ISS follows.

B. The condition \(\kappa \alpha \|X_S X_S^*\| < 2\) is necessary to ensure the convergence of LB algorithm in the noiseless case. This condition also guarantees the monotonic descent of \(\|X_S (\beta_{S,k} - \beta_S)\|\) before \(\bar{\tau}\).

5. Analysis of ISS Dynamics. The general idea to analyze differential inclusions in (1.2) and (1.3) is to associate these dynamics with some potential or Lyapunov functions, which control a fast convergence of solutions to the oracle estimator. The restricted strongly convex condition A1 suggests us that when the solution path \(\beta(t)\) evolves in the support set \(S\), a suitable choice of potential functions should be expected with exponentially fast decay, which enables us to estimate the stopping time of reaching sign consistency and small \(l_2\)-error.

The difficulty lies in that ISS dynamics are differential inclusions, hence we exploit differential inequalities of such a potential function to derive the bounds.

5.1. Potential function. One would like to study the dynamics of the following differential inclusion
\[
(5.1a) \quad \dot{\rho}_t + \frac{1}{\kappa} \dot{\beta}_t = -X^* X (\beta_t - \tilde{\beta}^*)
\]
\[
(5.1b) \quad \rho_t \in \partial \|\beta_t\|_1,
\]
where \(\tilde{\beta}^*\) is the oracle estimator. Assuming the right continuity of solutions and multiplying both sides above by \(\beta(t) - \tilde{\beta}^*\), one obtains a potential or Lyapunov function \(\Psi : \mathbb{R}^p \to \mathbb{R}^+_0\) associated with the dynamics
\[
\frac{d}{dt}(\Psi(\beta_t)) = -\frac{1}{n} \|X(\beta_t - \tilde{\beta}^*)\|_2^2.
\]
where
\begin{equation}
\Psi(\beta) = D(\tilde{\beta}, \beta) + \frac{\|\beta - \tilde{\beta}\|^2}{2\kappa}
\end{equation}
and $D(\tilde{\beta}, \beta)$ is the Bregman distance
\begin{equation}
D_V(\tilde{\beta}, \beta) := V(\tilde{\beta}) - V(\beta) - \langle \partial V(\beta), \tilde{\beta} - \beta \rangle
\end{equation}
induced by the particular convex function $V(\beta) = \|\beta\|_1$. As $n \ll p$, matrix $X$ has a large null-space, and to ensure the stationary point of the dynamics being the oracle solution, one must restrict the dynamics evolving outside the subspace $\ker(X)$.

5.2. Differential inequality with restricted exponential decay of potential. Define the following Oracle Dynamics as if an oracle discloses the true variable set $S$ such that we restrict our attention on a subspace defined by $S$,
\begin{equation}
\dot{\rho}'_S + \frac{1}{\kappa} \rho'_S = -X^*_S X_S (\beta'_S - \tilde{\beta}'_S), \quad \rho'_S(t) \in \partial \|\beta'_S(t)\|_1.
\end{equation}
Here $X^*_S X_S$ is a $s \times s$ symmetric matrix satisfying the strong convexity $X^*_S X_S \geq \gamma I_s$, which will lead to exponentially fast decay of potential function.

To reach this goal, our key treatment here is a differential inequality associated differential inclusion in Oracle Dynamics which is tight enough to ensure the exponential decay of potential function. This is a Bihari’s type [Bih56] nonlinear differential inequality, which generalizes the linear cases of Grönwall-Bellman inequalities [Gro19, Bel43]. In our treatment, a piecewise continuous bound is given which leads to the tight rates in this paper.

Lemma 5.1 (Generalized Bihari’s Inequality). The potential $\Psi$ of the Oracle Dynamics above satisfies the following differential inequality
\[ \frac{d}{dt}(\Psi(\beta'_S)) \leq -\gamma F^{-1}(\Psi(\beta'_S)), \]
where $F^{-1}$ is the right-continuous inverse of the following strictly increasing function
\begin{equation}
F(x) = \begin{cases} 
0 & 0 \leq x < \tilde{\beta}^2_{\min} \\
2x/\tilde{\beta}^2_{\min} & \tilde{\beta}^2_{\min} \leq x \leq 2\tilde{\beta}^2_{\max} \\
2\sqrt{x} & x \geq 2\tilde{\beta}^2_{\max}.
\end{cases}
\end{equation}
Such an inequality ensures a decrease of the potential function at a fast enough speed which leads to the following tight estimates on stopping time.

We are concerned with the following stopping time reaching sign-consistency and $l_2$-consistency of Oracle Dynamics, respectively. Define

$$\tilde{\tau}_1 := \inf\{t > 0 : \text{sign}(\beta'_S) = \text{sign}(\tilde{\beta}^*_S)\},$$

$$\tilde{\tau}_2(C) := \inf\left\{t > 0 : \|\beta'_S - \tilde{\beta}^*_S\|_2 \leq C\sqrt{\frac{s \log p}{n}} \right\}.$$ 

Equipped with the generalized Bihari’s inequality, one can build up the following bounds for stopping time on sign-consistency and $l_2$-consistency, respectively.

**Lemma 5.2.** The following bounds hold for the Oracle Dynamics (5.4)

$$\tilde{\tau}_1 \leq \frac{4 + 2 \log s}{\gamma \beta^*_\min} + \frac{1}{\kappa \gamma} \log \left(\frac{\|\tilde{\beta}^*_S\|_2}{\beta^*_\min}\right),$$

$$\tilde{\tau}_2(C) \leq \frac{4}{C \gamma} \sqrt{\frac{n}{\log p}} + \frac{1}{2 \kappa \gamma} \left(1 + \log \frac{n\|\tilde{\beta}^*_S\|_2^2}{C^2 s \log p}\right).$$

**Remark 5.1.**

A. $\tilde{\tau}_1 \leq O(\log s/\beta^*_\min)$ says that $\beta(t)$ will reach sign-consistency after $t \geq O(\log s/\beta^*_\min)$. The factor $\log s$ is due to the potential method above which converts a multidimensional dynamics into a one-dimensional differential inequality, and dropping potential exponentially from at least $\|\beta'_S\|_1 \geq s\beta^*_\min$ to 0 requires necessarily the $O(\log s)$ time.

B. $\tilde{\tau}_2(C) \leq O\left(\frac{1}{C^2} \sqrt{\frac{n}{p}}\right)$ says that $l_2$-consistency can be reached before $\tau = O\left(\sqrt{\frac{n}{p}}\right)$ as long as $C$ is a sufficiently large constant.

5.3. Sign-consistency and $l_2$-error bound. Now we are ready to reach the sign-consistency and $l_2$-error bound for $\beta(t)$ by setting $\tilde{\tau}_1 \leq \bar{\tau}$ and $\tilde{\tau}_2(C) \leq \bar{\tau}$, respectively. In these cases, Oracle Dynamics (5.4) $\beta'_S(t)$ meets the original path $\beta_S(t)$ when restricted on $S$. The complete proofs of Theorem 4.1 and its discrete version of Theorem 4.2 will be found in Appendix A, together with their supporting lemmas.
6. Data-dependent Stopping Rules for Bregman ISS. All the previous results enable us to select $\hat{\tau}$ as a stopping time which however depends on unknown parameters $\gamma, \eta$, and noise level $\sigma$, hence is not a data-dependent stopping rule. In this section we present two preliminary results with early stopping rules comparable to [CW11], which only depend on the noise level $\sigma$ and thus can be estimated from data. We leave it our future work to explore fully adaptive stopping rules.

In the following, define the residue $r(t) := y - X\beta(t)$. The first theorem adopts the stopping rule based on $\|r(t)\|_2$ and the second theorem is based on $\|Xr(t)\|_\infty$.

**Theorem 6.1.** Suppose

$$\beta^{*}_{\min} \geq \left( \frac{4\sigma}{\gamma^{1/2}} \sqrt{8\sigma (2 + \log s) \left( \max_{j \in T} \|X_j\|_n \right)} \right) \frac{\sqrt{\log p}}{n},$$

and

$$\beta^{*}_{\min} \geq \frac{2\sigma}{\sqrt{\gamma}} \left( \sqrt{1 + 2\sqrt{\frac{\log n}{n}}} + \sqrt{\frac{\log s}{n}} \right).$$

Then Bregman ISS with the stopping rule $\|r(t)\|_2 \leq \sigma \sqrt{n + 2\sqrt{n\log n}}$ selects the true subset $S$ with probability at least $1 - O(1/n)$.

**Remark 6.1.**

- This result is comparable to Theorem 7 in [CW11].
- The first condition on the minimum of magnitude of signals ensures the model selection consistency of the Bregman ISS path and thus indicates that one can find some $t$ along the path so that the residual term satisfies $\|r(t)\|_2 \leq \sigma \sqrt{n + 2\sqrt{n\log n}}$. Once the path achieves sign consistency, the Bregman ISS must stop.
- The second condition $\beta^{*}_{\min} \geq \frac{2\sigma}{\sqrt{\gamma}} \left( \sqrt{1 + 2\sqrt{\frac{\log n}{n}}} + \sqrt{\frac{\log s}{n}} \right)$ guarantees that one can not stop earlier before Bregman ISS achieves a full recovery. Note that as $n \to \infty$, one needs $\beta^{*}_{\min} \geq \frac{2\sigma}{\sqrt{\gamma}}$ which is a constant.

**Theorem 6.2.** In addition to (3.11), suppose

$$\beta^{*}_{\min} \geq \frac{2\sigma \max_i \|X_i\|_n}{\sqrt{n\gamma}} \sqrt{2(1 + c)s \log p} + 2\sigma \sqrt{\frac{\log s}{n\gamma}}.$$

Then Bregman ISS with the stopping rule $\|X^T r(t)\|_\infty \leq 2\sigma \sqrt{\max_i \|X_i\| \log p}$ ($\delta > 0$) selects the true subset $S$ with probability at least $1 - O(1/p + 1/n)$. 
Remark 6.2. This result is comparable to Theorem 8 in [CW11], though the lower bound \( \beta_{\min}^* \geq O(\sqrt{s \log p/n}) \) loses a factor \( \sqrt{s} \) here. As \( n \to \infty \), the lower bound can be arbitrarily small.

The remaining of this section presents the proofs of the theorems above.

Proof of Theorem 6.1. Lemma 3 in [CW11] or Lemma 5.2 in [CXZ09] shows that with probability at least \( 1 - \frac{1}{n} \), \( \epsilon \) is essentially \( l^2 \) upper bounded

\[
\|\epsilon\|_2 \leq \sigma \sqrt{n} + 2 \sqrt{n \log n}.
\]

Hence with the same probability,

\[
\|r(\tau^*)\| = \|(I - X_S(X_S^*X_S)^{-1}X_S)\epsilon\|_2 \leq \|\epsilon\|_2 \leq \sigma \sqrt{n + 2 \sqrt{n \log n}}
\]

We have now shown that the Bregman ISS stops once the path achieves sign consistency.

Next we are going to show that the algorithm will not stop whenever there is some \( i \in S \) such that \( \beta_i(t) = 0 \). By Lemma A.5,

\[
\|r_t\| \geq \|X_S(\tilde{\beta}_S^* - \beta_S(t))\|
\geq \sqrt{n \gamma} \|\tilde{\beta}_S^* - \beta_S(t)\|
\geq \sqrt{n \gamma} \beta_{\min}^*
\geq 2\sigma \sqrt{n + 2 \sqrt{n \log n}}
\]

provided that \( \beta_{\min}^* \geq 2\sigma \sqrt{\frac{1+2 \sqrt{\log n/n}}{\gamma}} \). Note that

\[
\|(X_S^*X_S)^{-1}X_S^*\epsilon\|_\infty \leq 2\sigma \sqrt{\frac{\log s}{n \gamma}}, \quad \text{w. p. at least } 1 - 2n^{-1},
\]

so it suffices to have \( \beta_{\min}^* \geq \frac{2\sigma(\sqrt{n + 2 \sqrt{n \log n}} + \sqrt{\log s})}{\sqrt{n \gamma}} \). \( \square \)

Proof of Theorem 6.2. By assumptions

\[
\beta_{\min}^* \geq \left( \frac{\sqrt{4\sigma (2 + \log s)}}{\gamma^{1/2}} \right)^2 \sqrt{\frac{8\sigma (2 + \log s) \max_{j \in T} \|X_j\|_n}{\gamma \eta}} \sqrt{\frac{\log p}{n}}.
\]

Hence, according to Theorem 4.2, the Bregman ISS achieves the sign consistency with high probability. Assume that at time \( \tau^* \), \( \beta(\tau^*) \) has the same sign as the underlying sparse signal \( \beta \). For each \( t \),

\[
r_t = (I - X_{S(t)})(X_{S(t)}^*X_{S(t)})^{-1}X_{S(t)}^*S \beta_S + \epsilon = s_t + n_t,
\]
where $s_t = (I - P_{S(t)})X_S\beta_S$ is the signal part of the residual and $n_t = (I - P_{S(t)})\epsilon$ is the noise part of the residual. Then $r_{\tau^*} = n_{\tau^*}$. Let $b_\infty = \sigma \sqrt{2(1 + c) \max_i \|X_i\| \log p}$.

\[
\text{Prob}(\|X^T n_t\|_\infty = \|X^T (I - P_t)\epsilon\|_\infty \geq b_\infty) \leq \sum_i \text{Prob}(\|X_i^T (I - P_t)\epsilon\|_\infty \geq b_\infty) \\
\leq \sum_i \text{Prob}(\|X_i^T \epsilon\|_\infty \geq b_\infty) \\
\leq \frac{2}{p^\gamma \sqrt{2 \log p}},
\]

which means the algorithm stops at $\tau^*$.

Next we are going to show that the algorithm will not stop whenever there is some $i \in A_t \subseteq S$ such that $\beta_i(t) = 0$. By Lemma A.5,

\[
\|X^T r_t\|_\infty = \|X^T [X_S(\tilde{\beta}^*_S - \beta_S(t)) + (I - P_S)\epsilon]\|_\infty, \\
\geq \|X_S^T [X_S(\tilde{\beta}^*_S - \beta_S(t)) + (I - P_S)\epsilon]\|_\infty, \\
= \|X_S^T X_S(\tilde{\beta}^*_S - \beta_S(t))\|_\infty, \\
X_S^T (I - P_S)\epsilon = 0, \\
\geq \frac{1}{\sqrt{s}} \|X_S^T X_S(\tilde{\beta}^*_S - \beta_S(t))\|_2, \\
\geq \frac{n\gamma}{\sqrt{s}} \|\tilde{\beta}^*_S - \beta_S(t)\|_2, \\
\geq \frac{n\gamma}{\sqrt{s}} \min_{\beta_{\min}} \geq b_\infty,
\]

provided that $\tilde{\beta}_{\min}^* \geq \frac{\sqrt{2b_\infty}}{n\gamma}$. Note that

\[
\|(X_S^* X_S)^{-1} X_S^* \epsilon\|_\infty \leq 2\sigma \sqrt{\frac{\log s}{n\gamma}}, \quad \text{w. p. at least } 1 - 2n^{-1},
\]

so it suffices to have

\[
\beta_{\min}^* \geq b_\infty + 2\sigma \sqrt{\frac{\log s}{n\gamma}} = \frac{\sigma (\max_i \|X_i\| \sqrt{2(1 + c)s \log p/\gamma + \sqrt{\log s}})}{\sqrt{n\gamma}},
\]

with probability at least $1 - O(p^{-1} + n^{-1})$. \hfill \Box

7. Experiments. In this section we provide some experimental results to illustrate the relations among LASSO, Bregman ISS (ISS) and Linearized Bregman iteration (LB).
In this experiment we choose \( n = 200, \ p = 100 \) and only the first \( s = 30 \) elements of \( \beta \) are nonzero \( (\beta_j = r_j + \text{sign}(r_j), \text{where } r_j \sim \mathcal{N}(0, 1), \ j = 1, \ldots, 30) \). Each sample \( x_i \) is drawn from the distribution \( \mathcal{N}(0, \Sigma_p) \). We choose \( \Sigma_p = (\sigma_{ij}) \), where \( \sigma_{ij} = 1 \) if \( i = j \), and \( \sigma_{ij} = 1/(3p) \) otherwise. In such a setting, the Irrepresentable (Incoherence) Condition holds with high probability, since \( \Sigma_p \) is nearly identity matrix. We choose noise level \( \sigma = 1 \) here, considering the choice that the magnitude of \( \beta_i \) is \( O(1) \).

Figure 1 is an example of regularization path of three methods. As \( \kappa \) goes bigger, the LB path becomes closer to that of ISS. For LB we choose \( \kappa \alpha = 1/2 \) such that the step size of gradient decent is \( 1/2 \), to satisfy the convergence condition. Note that if \( \alpha \) is too big, the solution is oscillating.

To compare the performance of three methods quantitatively, we choose the AUC of ROC curve, to measure the goodness of three regularization paths. ROC (receiver-operating-characteristic) curve is plotted by thresholding the regularization parameter \( \lambda \) in LASSO, \( t \) in ISS, or \( k \) in LB at different levels which create different true positive rates (TPR) and false positive rates (FPR):

\[
TPR = \frac{\#\{\text{Selected True Variables}\}}{\#\{\text{True Variables}\}}, \quad FPR = \frac{\#\{\text{Selected False Variables}\}}{\#\{\text{False Variables}\}}.
\]

ROC is a curve from \((0, 0)\) to \((1, 1)\). AUC (Area Under the Curve) means the area under the ROC curve. Large AUC values indicate that the signals are picked out earlier than noise on regularization paths. Repeating the experiments for 100 times, in Table 1 we report the mean AUC with standard deviations for the three methods at different noise levels. It shows that all the three methods work reasonably well in this example, while Bregman ISS performs slightly better than LASSO. As \( \kappa \) becomes bigger, the performance of LB gets closer to that of Bregman ISS. Notice that as noise level \( \sigma \) gets larger, all the methods have their performance decay since signal and noise get confused.

Table 1

Mean AUC (standard deviation) for three methods at different noise levels (\( \sigma \)): ISS has a slightly better performance than LASSO in terms of AUC and as \( \kappa \) increases, the performance of LB approaches that of ISS. As noise level \( \sigma \) increases, the performance of all the methods drops.
8. Discussion and Conclusion. In this paper, noisy sparse signal recovery is approached via two continuous dynamics, called Bregman ISS and Linearized Bregman ISS, where a discretization of the latter leads to the widely used Linearized Bregman Iteration algorithm. Equipped with an early stopping regularization, Bregman ISS can simultaneously achieve
model selection consistency and unbiased estimation. As a discretization of Linearized Bregman ISS paths, model selection consistency and minimax optimal $l_2$-error bounds for Linearized Bregman Iteration are also established. Some data-dependent stopping rules are given for Bregman ISS solution paths.

Future directions of our study include fully data-dependent stopping rules and generalization of our results in nonlinear settings.

APPENDIX A: PROOFS

A.1. Proof of Consistency of LBISS.

**Lemma A.1.** Assume that $X_S$ has full column rank.

(A) For all $t \leq \tau$, solution of (1.3) $\beta(t)$ contains no false positive if

$$
\|X^*_T X^*_S(\rho_S + \beta_S / \kappa) + tX^*_T P_T \epsilon\|_\infty < 1, \quad \forall t \leq \tau,
$$

where $P_T = I - X^*_S X^*_S$ is the projection operator onto the column space of $X_T$.

(B) Mean path $\bar{\beta}(\tau)$ is sign-consistent if

$$
\text{sign}(\bar{\beta}_S(\tau)) = \text{sign}(\beta^*_S + \Phi_S^{-1} X^*_S \epsilon - \frac{1}{\kappa} \Phi_S^{-1} (\rho_S(\tau) + \frac{1}{\kappa} \beta_S(\tau))) = \text{sign}(\beta^*_S)
$$

where $\Phi_S = X^*_S X_S = \frac{1}{n} X^*_S X_S$.

No-false-positivity and the sign-consistency for mean path in Theorem 4.1, directly follow this lemma.

**Proof of Lemma A.1.** Consider the differential inclusion (1.3)

$$
\dot{\rho} + \frac{1}{\kappa} \dot{\beta} = -\frac{1}{n} X^T(X\beta - y) = -X^*X(\beta - \beta^*) + X^*\epsilon
$$

Assume there exists a $\tau \geq 0$, such that for all $t \leq \tau$, solution path $\beta(t)$ contains no false-positive, i.e. $\text{supp}(\beta(t)) \subseteq S$. Then for all $t \leq \tau$,

(A.1) $\dot{\rho}_S + \dot{\beta}_S / \kappa = -X^*_S X_S (\beta_S - \beta^*_S) + X^*_S \epsilon$,

and

(A.2) $\dot{\rho}_T + \dot{\beta}_T / \kappa = -X^*_T X_S (\beta_S - \beta^*_S) + X^*_T \epsilon$.

From (A.1) one gets $-(\beta_S - \beta^*_S) = (X^*_S X_S)^{-1}(\dot{\rho}_S + \dot{\beta}_S / \kappa) - (X^*_S X_S)^{-1} X^*_S \epsilon$, which leads to the following equation by plugging into (A.2)

$$
\dot{\rho}_T + \dot{\beta}_T / \kappa = X^*_T X^*_S (\dot{\rho}_S + \dot{\beta}_S / \kappa) + X^*_T P_T \epsilon
$$
where \( P_T = I - P_S = I - X_S^TX_S^* \) is the projection matrix onto \( \text{im}(X_T) \).

Integration on both sides and setting
\[
\|\rho_T(t) + \beta_T(t)/\kappa\|_\infty = \|X_T^TX_S^t(\rho_S(t) + \beta_S(t)/\kappa) + tX_T^TP_T\epsilon\|_\infty < 1
\]
the first part follows from \( \beta_T(t) = \kappa \cdot \text{shrink}(\rho_T(t) + \beta_T(t)/\kappa, 1) \).

The second part is obtained by integration on \((A.1)\)
\[
\bar{\beta}_S(\tau) = \frac{1}{\tau} \int_0^\tau \beta_S(t) dt = \beta_S^* - \frac{1}{\tau} \Phi_S^{-1}(\rho_S(\tau)) + \frac{1}{\kappa} \beta_S(\tau) + \Phi_S^{-1}X_S^*\epsilon
\]
followed by taking \( \text{sign}(\bar{\beta}_S(\tau)) = \text{sign}(\beta_S^*) \). \( \square \)

**Lemma A.2.** Suppose \( \epsilon \sim N(0, \sigma^2 I_n) \), and \( X \in \mathbb{R}^{n \times p} \)
\[
\text{Prob}(\|X^T\epsilon\|_\infty > \sigma \sqrt{2(1 + \mu) \log p} \max_j \|X_j\|) \leq \frac{1}{p^{\mu} \sqrt{\pi} \log p}; \quad (A.3)
\]
\[
\text{Prob}(\|X^T\epsilon\|_2 > \sigma \sqrt{2(1 + \mu) \text{tr}(X^TX) \log p}) \leq \frac{1}{p^{\mu} \sqrt{\pi} \log p}. \quad (A.4)
\]

**Proof of Lemma A.2.** From the Gaussian tail probability bound,
\[
\text{Prob}(\|X^T\epsilon\|_\infty > \sigma \sqrt{2(1 + \mu) \log p} \max_j \|X_j\|) \leq 2 \frac{1}{\sqrt{2(1 + \mu) \log p} \sqrt{2\pi}} e^{-\frac{2(1 + \mu) \log p}{2}}
\]
\[
\leq \frac{1}{p^{1+\mu} \sqrt{\pi} \log p}.
\]
The first inequality is directly the union bound of index \( j \). The second inequality is obtained by the fact
\[
\{ \epsilon : \|X^T\epsilon\|_2 > \sigma \sqrt{2(1 + \mu) \text{tr}(X^TX) \log p} \} \subseteq \bigcup_j \{ \epsilon : |X_j^T\epsilon| > \sigma \sqrt{2(1 + \mu) \log p} \|X_j\| \},
\]
which ends the proof. \( \square \)

**Proof of Lemma 5.1.** Denote
\[
A_t = \{ i \in S | \text{sign}(\tilde{\beta}_i^*) \neq \text{sign}(\beta_i^t) \} \subseteq S.
\]
Noticed that
\[
\|\tilde{\beta}_S^* - \beta_S^t\|_2^2 \geq \sum_{i \in A_t} \tilde{\beta}_i^t^2 \geq \max_{i \in A_t} \{ \tilde{\beta}_i^t \} \sum_{i \in A_t} \|\tilde{\beta}_i^t\| = \max_{i \in A_t} \{ \tilde{\beta}_i^t D(\tilde{\beta}_S^*, \beta_i^t)/2, D(\tilde{\beta}_S^*, \beta_i^t)^2/4s \}
\]
and
\[ \| \tilde{\beta}_S^* - \beta_S^* \|_2 < \tilde{\beta}_{\min}^* \Rightarrow A_t = \emptyset \Rightarrow \tilde{\beta}_S^* = \beta_S^* \Rightarrow D(\tilde{\beta}_S^*, \beta_S^*) = 0 \]
then according to the definition of \( \Psi \) and \( F \), we have
\[ \Psi(\beta_S^*) = \frac{\| \tilde{\beta}_S^* - \beta_S^* \|_2^2}{2\kappa} + D(\tilde{\beta}_S^*, \beta_S^*) \leq F(\| \tilde{\beta}_S^* - \beta_S^* \|_2^2) \]
which implies
\[ F^{-1}(\Psi(\beta_S^*)) \leq \| \tilde{\beta}_S^* - \beta_S^* \|_2 \]
Combining the following result from right continuous differentiability
\[ \langle d\rho_t', \beta_S^* \rangle = 0 \]
and the strong convexity conditions of \( X_s^* X_s \), we have
\[ \frac{d}{dt}(\Psi(\beta_S^*)) = -\langle \beta_S^* - \tilde{\beta}_S^*, X_s^* X_s(\beta_S^* - \tilde{\beta}_S^*) \rangle \leq -\gamma \| \tilde{\beta}_S^* - \beta_S^* \|_2^2 \leq -\gamma F^{-1}(\Psi(\beta_S^*)), \]
as desired.

**Proof of Lemma 5.2.** From the generalized Bihari’s inequality
\[ \tau_1 \leq -\int_0^{\tau_1} \frac{\frac{d}{dt}(\Psi(\beta_S^*))}{\gamma F^{-1}(\Psi(\beta_S^*))} dt = \frac{1}{\gamma} \int_{\psi(0)}^{\psi(t_\infty)} \frac{dx}{F^{-1}(x)} \]
Note that \( \Psi(0) = \| \tilde{\beta}_S^* \|_1 + \frac{\| \tilde{\beta}_S^* \|_2^2}{2\kappa} \). so \( F^{-1}(\Psi(0)) \leq \| \tilde{\beta}_S^* \|_2^2 \). By continuity and monotonicity of \( F(x) \) on \( (\beta_{\min}, +\infty) \) and and \( \psi(t_\infty) \geq \beta_{\min}^2 \)

\[ \gamma \tau_1 \leq \int_{\beta_{\min}^2}^{\beta_{\min}^2 + 2\beta_{\min}} \frac{dx}{F^{-1}(x)} + \int_{\beta_{\min}^2}^{s\beta_{\min}^2} \frac{dF}{x} + \int_{s\beta_{\min}^2}^{\| \tilde{\beta} \|_2^2} \frac{dF}{x} \]
\[ \leq \int_{\beta_{\min}^2}^{\beta_{\min}^2 + 2\beta_{\min}} \frac{dx}{\beta_{\min}^2} + \int_{\beta_{\min}^2}^{s\beta_{\min}^2} \left( \frac{1}{2\kappa x} + \frac{2}{\beta_{\min}^2 x} \right) dx + \int_{s\beta_{\min}^2}^{\| \tilde{\beta} \|_2^2} \left( \frac{1}{2\kappa x} + \sqrt{s x^{-2}} \right) dx \]
\[ \leq \frac{4 + 2 \log s}{\beta_{\min}} + \frac{1}{\kappa} \log \left( \frac{\| \tilde{\beta} \|_2}{\beta_{\min}} \right) \]
Proof of \( \tau_2 \) is straightforward now. For \( t < \tau_2 \)
\[ \frac{d\Psi}{dt} \leq -\gamma |\tilde{\beta} - \beta|_2^2 \leq -\gamma \frac{C^2 s \log d}{n} \]
Let 
\[ \tilde{F}(x) = \frac{x}{2\kappa} + 2\sqrt{xs} \geq F(x) \quad \forall x > 0 \]

Let \( \tilde{F}^{-1} \) be the right-continuous inverse. Then \( \| \beta(t) - \tilde{\beta} \|^2 \geq \tilde{F}^{-1}(\Psi(\beta)) \geq \tilde{F}^{-1}(\Psi) \). By generalized Bihari’s inequality

\[ -\frac{1}{\gamma} \frac{d\Psi}{dt} \geq |\tilde{\beta} - \beta|^2 \geq \tilde{F}^{-1}(\Psi) \]

Therefore

\[ -\frac{1}{\gamma} \frac{d\Psi}{dt} \geq \max\{ \tilde{F}^{-1}(\Psi), \frac{C^2s \log d}{n} \} \]

Again, we have:

\[ \tilde{\tau}_2 \leq \frac{1}{\gamma} \int_{\Psi(\tilde{t}_2)}^{\Psi(0)} \frac{dx}{\max\{ \tilde{F}^{-1}(x), \frac{C^2s \log d}{n} \}} \]

Noted that

\[ \tilde{F}^{-1}(\Psi(0)) \leq F^{-1}(\Psi(0)) \leq |\tilde{\beta}|^2 \]

Therefore,

\[ \gamma \tilde{\tau}_2 \leq \int_0^{\tilde{F}(C^2s \log d/n)} \frac{dx}{\frac{C^2s \log d}{n}} + \int_{\tilde{F}(C^2s \log d/n)}^{\tilde{F}^{-1}(x)} \frac{dx}{\tilde{F}^{-1}(x)} \]

\[ \leq \int_0^{\tilde{F}(C^2s \log d/n)/2\kappa + 2Cs \sqrt{s \log d/n}} \frac{dx}{C^2s \log d/n} + \int_{C^2s \log d/n}^{\tilde{F}^{-1}(x)} \frac{dx}{\tilde{F}^{-1}(x)} \]

\[ \leq \frac{1}{2\kappa} + \frac{2}{C} \sqrt{\frac{n \log d}{C^2s \log d/n}} + \int_{C^2s \log d/n}^{\tilde{F}^{-1}(x)} \left( \frac{1}{2\kappa x} + \frac{\sqrt{s}}{x^{3/2}} \right) dx \]

\[ \leq \frac{4}{C} \sqrt{\frac{n \log d}{C^2s \log d/n}} + \frac{1}{2\kappa} \left( 1 + \log \frac{n |\tilde{\beta}|^2}{C^2s \log d} \right) \]

which gives the bounds.

\[ \square \]

**Proof of Theorem 4.1.**

\[ A = \{ \epsilon : \| X_S X_S^* X_S^{-1} X_S^\epsilon \|_2 > 2\sigma \sqrt{s \log n} \} \]

\[ B = \{ \epsilon : \| (X_S^* X_S)^{-1} X_S^\epsilon \|_\infty > 2\sigma \sqrt{\frac{\log p}{n\gamma}} \} \]

\[ C = \{ \epsilon : \| X_T^* P_T \epsilon \|_\infty > 2\sigma \sqrt{\frac{\log p}{n}} \max_{j \in T} \| X_j \|_n \} \]
Note $tr(X_S(X_S^*X_S)^{-1}X_S^*) = s$, $(X_S^*X_S)^{-1}X_S^* \cdot X_S(X_S^*X_S)^{-1} = (X_S^*X_S)^{-1} \preceq 1/\gamma$, and $X_T^*P_T \cdot P_T X_T \preceq X_T^*X_T$, using Lemma A.2, we have

$$P_{\text{rob}(A)} \leq \frac{1}{n\sqrt{\pi \log n}}, \quad P_{\text{rob}(B)} \leq \frac{1}{p\sqrt{\pi \log p}}, \quad P_{\text{rob}(C)} \leq \frac{1}{p\sqrt{\pi \log p}}.$$  

(1) (no-false-positivity for $\beta(t)$ up to $\tau$) First consider the LB-ISS

(A.5) \[
\frac{d\rho}{dt} + \frac{1}{\kappa} \frac{d\beta_S}{dt} = -X_S^*X_S(\beta_S - \tilde{\beta}_S)
\]

where $\tilde{\beta}_S = \beta_S^* + (X_S^*X_S)^{-1}X_S^* \epsilon$. It is easy to conclude $\|X_S(\tilde{\beta}_S - \beta_S)\|_2$ is monotonically decreasing based on the following observation

$$\frac{d}{dt} \frac{\|X_S(\tilde{\beta}_S - \beta_S)\|_2^2}{2n} = -\left< \frac{d\rho}{dt}, \frac{d\beta_S}{dt} \right> - \frac{1}{\kappa} \left\| \frac{d\beta_S}{dt} \right\|_2 \leq 0$$

using $\langle d\rho(t)/dt, d\beta_S(t)/dt \rangle = 0$ from the assumption of Bregman ISS paths. On the set $A^c \cup B^c$, we have

$$\|\beta_S\|_\infty \leq \|\tilde{\beta}_S\|_\infty + \|\tilde{\beta}_S - \beta_S(t)\|_2$$

$$\leq \tilde{\beta}_\text{max} + \frac{\|X_S(\tilde{\beta}_S - \beta_S(t))\|_2}{\sqrt{n\gamma}}$$

$$\leq \tilde{\beta}_\text{max} + \frac{\|X_S\tilde{\beta}_S\|_2}{\sqrt{n\gamma}}$$

$$\leq \beta_\text{max}^* + 2\sigma \sqrt{\frac{\log p}{\gamma n}} + \frac{\|X_S\beta_\text{max}^*\|_2 + 2\sigma \sqrt{s \log n}}{\sqrt{n\gamma}}$$

Denote this upper bound as $B$. Returning to the original problem, by Lemma A.1, it suffices to have for all $t \leq \tau$,

$$1 > \|X_T^*X_S^\dagger(\rho_S + \beta_S/\kappa) + tX_T^*P_T\epsilon\|_\infty$$

The first part

$$\|X_T^*X_S^\dagger(\rho_S + \beta_S/\kappa)\|_\infty \leq (1 - \eta)(1 + \|\beta_S\|_\infty/\kappa) \leq 1 - (1 - B/\kappa\eta)\eta$$

$t \leq \tau : = \frac{1 - B/\kappa\eta}{2} \eta^{-1} \sqrt{n/\log p} \left( \max_{j \in T} \|A_j\| \right)^{-1} = O(\eta^{-1} \sqrt{n/\log p})$.

On the set $C^c$, we have $t\|X_T^*P_T\epsilon\|_\infty < (1 - B/\kappa\eta)\eta$. 
(2) (no-false-negativity for the mean path) it suffices to ensure
\[ \beta_{\min}^* > \| \Phi_S^{-1} X_S^* \varepsilon \|_\infty + \frac{1}{\tau} \| \Phi_S^{-1} (\rho_S + \beta_S / \kappa) \|_\infty. \]

Where \( \Phi_S = X_S^* X_S \). The second part on the right hand side is \( \| \frac{1}{\tau} \Phi_S^{-1} (\rho_S + \beta_S / \kappa) \|_\infty \leq \frac{1}{\tau} \| \Phi_S^{-1} \|_\infty (1 + B / \kappa) \). The first part is bounded on the set \( B^c \).

(3) (\( l_2 \)-error bound) Lemma 5.2 implies if \( C > \frac{8 \sigma (\max_{j \in T} \| X_j \|_n)}{\eta \gamma} \), when \( \kappa \) is big enough, we have
\[
\tilde{t}_2(C) \leq \frac{4}{C \gamma} \sqrt{\frac{n}{\log p}} + \frac{1}{2 \kappa \gamma} \left( 1 + \log \frac{n \| \hat{\beta} \|_2^2}{C^2 s^2 \log p} \right)
\leq \frac{4}{C \gamma} \sqrt{\frac{n}{\log p}} + \frac{1}{2 \kappa \gamma} \left( 1 + \log \frac{n \| \beta^* \|_2^2 + 4 \sigma^2 s \log p / \gamma}{C^2 s \log p} \right)
\leq \frac{4 + 2 \log s}{\gamma \beta_{\min}} + \frac{1}{\kappa \gamma} \log \left( \frac{\| \hat{\beta} \|_2}{\beta_{\min}} \right) \leq \frac{8 + 4 \log s}{\beta_{\min} \gamma} + \frac{1}{\kappa \gamma} \log \left( \frac{3 \| \beta^* \|_2}{\beta_{\min}} \right)
\leq \frac{4 + 2 \log s}{\gamma \beta_{\min}} + \frac{1}{\kappa \gamma} \log \left( \frac{3 \| \beta^* \|_2}{\beta_{\min}} \right) \leq \frac{8 + 4 \log s}{\beta_{\min} \gamma} + \frac{1}{\kappa \gamma} \log \left( \frac{3 \| \beta^* \|_2}{\beta_{\min}} \right)
\leq \frac{8 + 4 \log s}{\beta_{\min} \gamma} + \frac{1}{\kappa \gamma} \log \left( \frac{3 \| \beta^* \|_2}{\beta_{\min}} \right)
\leq \frac{4 + 2 \log s}{\gamma \beta_{\min}} + \frac{1}{\kappa \gamma} \log \left( \frac{\| \hat{\beta} \|_2}{\beta_{\min}} \right) \leq \tilde{t}_2(C) \leq C \sqrt{\frac{\log p}{n}}.
\]

Note that with high probability
\[ \| \beta_S (\tau) - \hat{\beta}_S \|_2 \leq C \sqrt{\frac{\log p}{n}}. \]

Thus \( \exists \tau \in [0, \tilde{t}_2(C)] \)
\[ \| \beta_S (\tau) - \hat{\beta}_S \|_2 \leq C \sqrt{\frac{\log p}{n}}. \]

(4) (Sign Consistency for \( \beta_t \)) The condition
\[ \beta_{\min}^* \geq \frac{4 \sigma}{\gamma \gamma^1/2} \sqrt{\frac{\log p}{n}} \]
implies that \( \hat{\beta} \) has the same sign as \( \beta^* \) as well as \( 1/2 | \beta_{\min}^* | \leq | \hat{\beta}_i | \leq 3/2 | \beta_{\min}^* | \) for each component \( i \). Thus sign consistency is reached when \( \tilde{t}_\infty \leq \tilde{t}_2(C) \), or
\[
\frac{4 + 2 \log s}{\gamma \beta_{\min}} + \frac{1}{\kappa \gamma} \log \left( \frac{\| \hat{\beta} \|_2}{\beta_{\min}} \right) \leq \frac{8 + 4 \log s}{\beta_{\min} \gamma} + \frac{1}{\kappa \gamma} \log \left( \frac{3 \| \beta^* \|_2}{\beta_{\min}} \right)
\leq \frac{8 + 4 \log s}{\beta_{\min} \gamma} + \frac{1}{\kappa \gamma} \log \left( \frac{3 \| \beta^* \|_2}{\beta_{\min}} \right)
\leq \frac{8 + 4 \log s}{\beta_{\min} \gamma} + \frac{1}{\kappa \gamma} \log \left( \frac{3 \| \beta^* \|_2}{\beta_{\min}} \right)
\leq \frac{8 + 4 \log s}{\beta_{\min} \gamma} + \frac{1}{\kappa \gamma} \log \left( \frac{3 \| \beta^* \|_2}{\beta_{\min}} \right)
\leq \frac{4 + 2 \log s}{\gamma \beta_{\min}} + \frac{1}{\kappa \gamma} \log \left( \frac{\| \hat{\beta} \|_2}{\beta_{\min}} \right) \leq \frac{8 + 4 \log s}{\beta_{\min} \gamma} + \frac{1}{\kappa \gamma} \log \left( \frac{3 \| \beta^* \|_2}{\beta_{\min}} \right)
\]

which is ensured by \( \kappa \) big enough and
\[ \beta_{\min}^* \geq 2 \hat{\beta}_{\min} \geq \left( \frac{4 \sigma}{\gamma \gamma^1/2} \sqrt{\frac{8 \sigma (2 + \log s) (\max_{j \in T} \| X_j \|_n)}{\eta \gamma}} \right) \sqrt{\frac{\log p}{n}}. \]

This completes the proof. \( \square \)
A.2. Proof of Consistency of Linearized Bregman Iterations.

First of all, we give a discrete version of generalized Bihari’s inequality which is useful for Linearized Bregman iterations (1.4).

**Lemma A.3** (Discrete Generalized Bihari’s inequality). Consider the LB

\((\rho_{k+1} - \rho_k) + (\beta_{k+1} - \beta_k)/\kappa = -\alpha_k X^*_S X_S (\beta_k - \bar{\beta})\)

where \(X^*_S X_S \geq \gamma I\). Let the potential (or Lyapunov) function be

\[\Psi_k = D(\bar{\beta}, \beta_k) + \frac{||\beta_k - \bar{\beta}||^2}{2\kappa}\]

Then the following difference inequality holds

\[\Psi_{k+1} - \Psi_k \leq -\alpha_k \gamma (1 - \kappa \alpha_k ||X^*_S X_S||/2) F^{-1}(\Psi_k)\]

where \(F\) is defined by (5.5).

**Proof of Lemma A.3.** Similar to continue case, we have

\[||\beta_k - \bar{\beta}||^2 \geq F^{-1}(\Psi_k)\]

Since \(\ell_1\)-norm is homogeneous of degree 1, its subgradient \(\rho \in \partial ||\beta||_1\) satisfies \(\langle \rho, \beta \rangle = ||\beta||_1\). Multiplying \(\beta_k - \bar{\beta}\) on the both sides of iteration equation, it leads to

\[\Psi_{k+1} - \Psi_k + (\rho_{k+1} - \rho_k) \beta_k - ||\beta_{k+1} - \beta_k||^2/2\kappa = -\alpha_k \langle \beta_k - \bar{\beta}, X^*_S X_S (\beta_k - \bar{\beta})\rangle\]

Note that for \(i \in S\), \((\rho_{k+1}^{(i)} - \rho_k^{(i)}) \beta_{k+1}^{(i)} = ||\beta_{k+1}^{(i)}|| - \rho_k^{(i)} \beta_{k+1}^{(i)} \geq 0\)

\[\leq \kappa \alpha_k ||X^*_S X_S (\beta_k - \bar{\beta})||^2\]

\[\Psi_{k+1} - \Psi_k \leq -\frac{\alpha_k}{n} \langle X_S(\beta_k - \bar{\beta}), X_S(\beta_k - \bar{\beta})\rangle + \frac{\alpha_k^2}{2n^2} \langle X^*_S X_S (\beta_k - \bar{\beta}), X^*_S X_S (\beta_k - \bar{\beta})\rangle\]

\[= -\frac{\alpha_k}{n} \langle X_S(\beta_k - \bar{\beta}), (I - \kappa \alpha_k X^*_S X_S/2) X_S(\beta_k - \bar{\beta})\rangle\]

\[\leq -\frac{\alpha_k}{n} (1 - \kappa \alpha_k ||X^*_S X_S||/2) ||X_S(\beta_k - \bar{\beta})||^2\]

\[\leq -\alpha_k \gamma (1 - \kappa \alpha_k ||X^*_S X_S||/2) ||\beta_k - \bar{\beta}||^2\]

\[\leq -\alpha_k \gamma (1 - \kappa \alpha_k ||X^*_S X_S||/2) F^{-1}(\Psi_k)\]

which gives the result. \(\square\)
Next we present a discrete stopping time bound from the inequality above.

**Lemma A.4 (Discrete Stopping Time Bounds).** Consider the LB

\[
\rho_{k+1} - \rho_k + (\beta_{k+1} - \beta_k) / \kappa = -\alpha_k X_S^* X_S (\beta_k - \tilde{\beta})
\]

where \(X_S^* X_S \geq \gamma I\) and \(\alpha_k \leq \alpha, \ \forall k\).

Define

\[
\tilde{\tau}_1 := \inf \left\{ \sum_{t=0}^{k-1} \alpha_t : \text{sign}(\beta_k) = \text{sign}(\tilde{\beta}) \right\}
\]

and

\[
\tilde{\tau}_2(C) := \inf \left\{ \sum_{t=0}^{k-1} \alpha_t : ||\beta_k - \tilde{\beta}||_2 \leq C \sqrt{\frac{s \log p}{n}} \right\}
\]

Then the following bounds hold,

\[
\tilde{\tau}_\infty \leq \frac{4 + 2 \log s}{\tilde{\gamma} \beta_{\min}} + \frac{1}{\kappa \tilde{\gamma}} \log \left( \frac{||\tilde{\beta}||_2}{\beta_{\min}} \right) + 3 \alpha
\]

\[
\tilde{\tau}_2(C) \leq \frac{4}{C \tilde{\gamma}} \sqrt{\frac{n}{\log p}} + \frac{1}{2 \kappa \tilde{\gamma}} \left( 1 + \log \frac{n ||\tilde{\beta}||_2^2}{C^2 s \log p} \right) + 2 \alpha
\]

where \(\tilde{\gamma} = \gamma (1 - \kappa \alpha ||X_S X_S^*|| / 2)\)

**Remark A.1.** Taking \(\alpha \to 0\), it recovers the stopping time bounds in continuous case, Lemma 5.2.

**Proof of Lemma A.4.** Consider

\[
\Psi_k = D(\tilde{\beta}, \beta_k) + \frac{||\beta_k - \tilde{\beta}||^2}{2 \kappa}
\]

For a uniform upper bound on step sizes \(\alpha_t \leq \alpha\), by the discrete Bihari’s inequality in Lemma A.3

\[
\Psi_{k+1} - \Psi_k \leq -\alpha_k \tilde{\gamma} F^{-1}(\Psi_k) \leq -\alpha_k \tilde{\gamma} \tilde{F}^{-1}(\Psi_k)
\]

where \(\tilde{\gamma} = \gamma (1 - \kappa \alpha ||X X^*|| / 2)\) and \(\tilde{F}(x) = \frac{x}{2 \kappa} + 2 \sqrt{ax} \geq F(x), \ \forall x > 0\).

For \(k\) such that \(\Psi_k \geq 2 \tilde{\beta}_{\min} + \tilde{\beta}_{\min}^2 / 2 \kappa\), denote \(L_k = F^{-1}(\Psi_k)\), which is non-increasing. Define \(t_m = \sum_{t=0}^{m-1} \alpha_t\). Let \(n_1 = \sup \{ n : L_n > s \tilde{\beta}_{\min}^2 \}\), then

\[
\tilde{\gamma} \alpha_k \leq \frac{F(L_k) - F(L_{k+1})}{L_k}
\]
then for $0 \leq k \leq n_1 - 1$,
\[
\frac{F(L_k) - F(L_{k+1})}{L_k} \leq \left( \frac{\log L_k}{2\kappa} - 2 \sqrt{\frac{s}{L_k}} \right) - \left( \frac{\log L_{k+1}}{2\kappa} - 2 \sqrt{\frac{s}{L_{k+1}}} \right)
\]
This is because of
\[
\frac{L_k - L_{k+1}}{L_k} \leq \log\left( \frac{L_k}{L_{k+1}} \right)
\]
using $1 - x \leq -\log x$ for $x \leq 1$, and
\[
\frac{\sqrt{T_k} - \sqrt{T_{k+1}}}{L_k} \leq \frac{\sqrt{T_k} - \sqrt{T_{k+1}}}{\sqrt{T_k} / \sqrt{T_{k+1}}} = \frac{1}{\sqrt{T_{k+1}}} - \frac{1}{\sqrt{T_k}}
\]
\[
\hat{\gamma} t_{n_1} \leq \left( \frac{\log L_{n_0}}{2\kappa} - 2 \sqrt{\frac{s}{L_{n_0}}} \right) - \left( \frac{\log L_{n_1}}{2\kappa} - 2 \sqrt{\frac{s}{L_{n_1}}} \right)
\]
\[
\leq \left( \frac{\log \|\hat{\beta}\|^2}{2\kappa} - 2 \sqrt{\frac{s}{\|\hat{\beta}\|^2}} \right) - \left( \frac{\log s\beta_{min}^2}{2\kappa} - 2 \sqrt{\frac{s}{s\beta_{min}^2}} \right)
\]
Let $n_2 = \sup\{ n : L_n > \beta_{min}^2 \}$,
\[
\hat{\gamma} \alpha_k \leq \frac{F(L_k) - F(L_{k+1})}{L_k}
\]
Then similarly, we have
\[
\hat{\gamma}(t_{n_2} - t_{n_1+1}) \leq \left( \frac{1}{2\kappa} + \frac{2}{\beta_{min}} \right)(\log L_{n_1+1} - \log L_{n_2})
\]
\[
\leq \left( \frac{1}{2\kappa} + \frac{2}{\beta_{min}} \right)(\log s\beta_{min}^2 - \log \beta_{min}^2)
\]
Let $n_3 = \sup\{ n : \Psi_n > \beta_{min}^2 / 2\kappa \}$
\[
\hat{\gamma}(t_{n_3} - t_{n_2+1}) \leq \sum_{k=n_2+1}^{n_3-1} \frac{\Psi_k - \Psi_{k+1}}{\beta_{min}^2} \leq \frac{\beta_{min}^2}{2n} + 2\beta_{min} - \frac{\beta_{min}^2}{2n}
\]
\[
= \frac{2}{\beta_{min}}
\]
To sum up, we have
\[ \tilde{\tau}_1 \leq t_{n_{s+1}} \leq \frac{4 + 2 \log s}{\tilde{\gamma} \tilde{\beta}_{\min}} + \frac{1}{\kappa \tilde{\gamma}} \log \left( \frac{\|\tilde{\beta}\|_2}{\tilde{\beta}_{\min}} \right) + 3\alpha \]

Similarly, we have
\[ \tilde{\tau}_2(C) \leq 4 \sqrt{\frac{n}{\log d}} + \frac{1}{2\kappa \tilde{\gamma}} \left( 1 + \log \frac{n|\tilde{\beta}|_2^2}{C^2 s^2 \log d} \right) + 2\alpha, \]
which ends the proof. \hfill \Box

**Proof of Theorem 4.2.** The proof is the same to the continue case. The only difference is the decreasing of \( \|X(\beta_k - \tilde{\beta})\|_2 \) needs the condition \( \kappa\alpha\|X_SX_S^*\| < 2 \).

Consider the LB
\[
(\rho_{k+1} - \rho_k) + (\beta_{k+1} - \beta_k)/\kappa = -\alpha_kX_S^*X_S(\beta_k - \tilde{\beta})
\]
where \( X_S^*X_S \geq \gamma I \).

\[
\|X_S(\beta_{k+1} - \tilde{\beta})\|^2 - \|X_S(\beta_k - \tilde{\beta})\|^2 \\
= \|X_S(\beta_{k+1} - \beta_k)\|^2 + 2(\beta_{k+1} - \beta_k)^T X_S^*X_S(\beta_k - \tilde{\beta}) \\
= \|X_S(\beta_{k+1} - \beta_k)\|^2 - 2n/\alpha_k(\beta_{k+1} - \beta_k)^T [(\rho_{k+1} - \rho_k) + (\beta_{k+1} - \beta_k)/\kappa] \\
\leq \|X_S(\beta_{k+1} - \beta_k)\|^2 - 2n/\alpha_k(\beta_{k+1} - \beta_k)^T(\beta_{k+1} - \beta_k)/\kappa \\
= n(\beta_{k+1} - \beta_k)^T (X_S^*X_S - 2/\alpha_k \kappa)(\beta_{k+1} - \beta_k) \\
\leq 0,
\]
where we have used \( \|X_SX_S^*\| = \|X_S^*X_S\| \). Hence \( \|X_S(\tilde{\beta}_S - \beta_k)\|_2 \) is monotonically nonincreasing. \hfill \Box

Note that this implies that \( \|r_t\| := \|y - X\beta_t\| \) is monotonically nonincreasing for all \( t \in (0, \tilde{\tau}) \). The following lemma makes it precise.

**Lemma A.5.** For \( t \in [0, \tilde{\tau}] \), the residue admits an orthogonal decomposition
\[
\|r_t\|^2 = \|y - X\beta_t\|^2 = \|X_S(\tilde{\beta}_S - \beta_S(t))\|^2 + \|P_T\tilde{\varepsilon}\|^2
\]
and is monotonically nonincreasing.
PROOF. By Pythagorean Theorem,
\[
\|r_t\|^2 = \|X_S(\beta^* - \beta_t) + \varepsilon\|^2 = \|P_S X_S(\beta^* - \beta_t) + P_S \varepsilon\|^2 + \|(I - P_S)\varepsilon\|^2 \\
= \|X_S(\beta^* - \beta_t) + X_S(X_S^* X_S)^{-1} X_S^* \varepsilon\|^2 + C_{\varepsilon,S} \\
= \|X_S(\tilde{\beta}_S^* - \beta_S(t))\|^2 + C_{\varepsilon,S}
\]
and the conclusion follows from that \(\|X_S(\tilde{\beta}_S^* - \beta_S(t))\|\) is monotonically nonincreasing.
